Executive Summary

The United States Army Corps of Engineers Baltimore District on behalf of the Army National Guard (ARNG)-Installations & Environment Division, Cleanup Branch contracted AECOM Technical Services, Inc. (AECOM) to perform *Preliminary Assessments (PAs) and Site Inspections (SIs) for Perfluorooctanesulfonic acid (PFOS) and Perfluorooctanoic acid (PFOA) Impacted Sites at ARNG Facilities Nationwide*. The ARNG is assessing potential effects on human health related to processes at facilities that used per- and poly-fluoroalkyl substances (PFAS), primarily in the form of aqueous film forming foam released as part of firefighting activities, although other PFAS sources are possible.

AECOM completed a PA for PFAS at the Portland Air National Guard (PANG) Base Enclave in Portland, Oregon, to assess potential PFAS release areas and exposure pathways to receptors. The performance of this PA included the following tasks:

- Reviewed data resources to obtain information relevant to suspected PFAS releases
- Conducted a site visit on 14 September 2018
- Interviewed current Oregon ARNG personnel during the site visit as well as environmental managers and operations staff
- Completed visual survey inspections to confirm absence of PFAS-related activities and documented with photographs

No Area(s) of Interest related to potential PFAS use, release, or storage were identified at the PANG Base Enclave during the PA; however, several potential PFAS sources are located adjacent to the facility. (**Figure ES-1**). Based on facility history and interviews with various personnel, there is the potential for exposure to PFAS contamination in surface water and groundwater under the facility from adjacent sources; however; there is no potential for exposure to PFAS contamination in surface soil, subsurface soil, or sediment.

1. Introduction

1.1 Authority and Purpose

The United States (US) Army Corps of Engineers (USACE) Baltimore District on behalf of the Army National Guard (ARNG)-Installations & Environment Division, Cleanup Branch contracted AECOM Technical Services, Inc. (AECOM) to perform *Preliminary Assessments (PAs) and Site Inspections (SIs) for Perfluorooctanesulfonic acid (PFOS) and Perfluorooctanoic acid (PFOA) Impacted Sites at ARNG Facilities Nationwide* under Contract Number W912DR-12-D-0014, Task Order W912DR17F0192, issued 11 August 2017, and Modification 01 issued 30 September 2017. The ARNG is assessing potential effects on human health related to processes at facilities that used per- and poly-fluoroalkyl substances (PFAS), primarily in the form of aqueous film forming foam (AFFF) released as part of firefighting activities, although other PFAS sources are possible. In addition, the ARNG is assessing businesses or operations adjacent to the ARNG facility (not under the control of ARNG) that could potentially be responsible for a PFAS release.

PFAS are classified as emerging environmental contaminants that are garnering increasing regulatory interest due to their potential risks to human health and the environment. PFAS formulations contain highly diverse mixtures of compounds. Thus, the fate of PFAS compounds in the environment varies. The regulatory framework at both federal and state levels continues to evolve. The US Environmental Protection Agency (USEPA) issued Drinking Water Health Advisories for PFOA and PFOS in May 2016, but there are currently no promulgated national standards regulating PFAS in drinking water. In the absence of federal maximum contaminant levels, some states have adopted their own drinking water standards for PFAS. The Oregon Department of Environmental Quality has set Pollutant Initiation Levels (PILs) for PFAS/PFOA, which are not water quality standards (DEQ, 2017). According to OAR 340-045-0100, only facilities that operate under National Pollution Discharge Elimination System and Water Pollution Control Facility permits in Oregon are required to analyze effluent for PFAS/PFOA and report concentrations that exceed the PILs.

This report presents findings of a PA for PFAS at the Portland Air National Guard (PANG) Base Enclave in Portland, Oregon, in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), as amended, the National Oil and Hazardous Substances Pollution Contingency Plan (40 Code of Federal Regulations Part 300), and USACE requirements and guidance.

This PA documents potential locations where PFAS may have been used, stored, or released into the environment at the PANG Base Enclave. The term PFAS will be used throughout this report to encompass all PFAS chemicals being evaluated, including PFOS and PFOA, which are key components of AFFF.

1.2 Preliminary Assessment Methods

The performance of this PA included the following tasks:

- Reviewed data resources to obtain information relevant to suspected PFAS releases
- Conducted a site visit on 14 September 2018
- Interviewed current Oregon ARNG (ORARNG) personnel during the site visit as well as ORARNG environmental managers and operations staff
- Completed visual survey inspections to confirm absence of PFAS-related activities and documented with photographs

1.3 Report Organization

This report has been prepared in accordance with the USEPA *Guidance for Performing Preliminary Assessments under CERCLA* (USEPA, 1991). The report sections and descriptions of each are:

- **Section 1** – **Introduction:** identifies the project purpose and authority and describes the facility location, environmental setting, and methods used to complete the PA
- **Section 2** – **Fire Training Areas:** describes the fire training areas (FTAs) at the facility identified during the site visit
- **Section 3** – **Non-Fire Training Areas:** describes other locations of PFAS releases at the facility identified during the site visit
- **Section 4** – **Emergency Response Areas:** describes areas of AFFF release at the facility, specifically in response to emergency situations
- **Section 5** – **Adjacent Sources:** describes sources of PFAS release adjacent to the facility that are not under the control of ARNG
- **Section 6** – **Conceptual Site Model:** describes the pathways of PFAS transport and receptors for the Areas of Interest (AOIs) and the facility
- **Section 7** –**Conclusions:** summarizes the data findings and presents the conclusions of the PA
- **Section 8** – **References:** provides the references used to develop this document
- **Appendix A** – Data Resources
- **Appendix B** – Preliminary Assessment Documentation
- **Appendix C** – Photographic Log

1.4 Facility Location and Description

The PANG Base Enclave is in the southeastern portion of the Portland International Airport (PDX) in Portland, Oregon in Multnomah County (**Figure 1-1**). The facility is on the northeastern city limits of Portland, on the banks of the Columbia River across from Vancouver, Washington. The city of Portland, Gresham, Oregon City, Scappoose, and Beaverton lie within 10 miles of PANG Base Enclave.

A small military service depot was built in 1940, in an area which is now operated by the Oregon Air National Guard (ORANG). From 1941 until 1945, the facility was designated as Portland Army Air Base. Following World War II, in approximately 1946, a large portion of the property was converted to operation as an Air National Guard Base, and still maintains that status at present time (OTC, 1996). In 1949, the ARNG was granted a license from the ANG, with permission from the Port of Portland, to construct, maintain, and operate several buildings including an aviation hangar. The ARNG lease was renewed in 1960 and in 1961, a deed was granted by the Port of Portland to the National Guard for construction of an armory, now known as Jackson Armory.

The PANG Base is constructed on approximately 245 acres of land leased from the Port of Portland, a small portion of which the PANG Base Enclave, including Jackson Armory, is a tenant. The current lease agreement between the ANG and ARNG expires in 2029 (ERM, 2003). See **Appendix A** for real estate documents.

1.5 Facility Environmental Setting

PANG Base Enclave is in the floodplain of the Columbia River on a topographic boundary known as the Columbia Plateau in the eastern portion of the Portland Basin. The city of Portland sits on the confluence of the Willamette and Columbia Rivers and is bounded to the north-northeast by the Columbia River, to the west by the Coast Ranges and the Willamette River, and to the east by the Cascade Range (O'Connor et. al, 2001). The elevation of the facility is 30 to 45 feet above mean sea level. The terrain around the PANG Base Enclave has little to no natural topography and gently slopes north toward the Columbia River.

1.5.1 Geology

Multnomah County and Portland, Oregon are located in the northern edge of the Willamette Valley physiographic province, on a topographic boundary known as the Columbia Plateau. The Willamette Valley is a drainage basin that is roughly 170 miles long from north to south and encompasses nearly 12,000 square miles. The Willamette River Basin can be further divided into three parts: (1) The Oregon Coast Range, (2) the Puget Trough section (which includes 25% of the Valley, including the Columbia Plateau), and (3) the Middle Cascade Mountains lowlands section (Trimble, 1963).

The Columbia Plateau is punctuated by several small buttes and the Boring Hills, a complex system where small Eocene volcanic cones mix with blocks uplifted by faulting. Late Miocene fluvial deposits from the Cascade Mountain Range also mark the region (Madin, 2009; Leidos, 2018). PANG Base Enclave is situated on quaternary age alluvium comprised of floodplain and terraced bedded sands, silts, and clays roughly 50 to 200 feet in thickness (O'Connor et. al, 2001). Lacustrine deposits of late Pleistocene age form an extensive fill in parts of the floodplain to the south of the facility, emplaced by flood waters from the sudden release of glacial Lake Missoula (O'Connor et. al, 2001). Artificial fill can also be found in localized areas to the north of, under, and directly east and west of PANG Base Enclave.

The alluvium and lacustrine deposits overlie the Troutdale Formation, an early Pliocene formation deposited in structural basins formed by the warping of the Columbia River basalt (Vaccaro, 1990). Under the PANG Base Enclave, the Troutdale Formation is roughly 800 to 900 feet thick and comprised mostly of well-sorted, coarse-grained sandstone and a conglomerate (well-rounded quartzite pebbles set in fine clay matrix) of Columbia River provenance. Localized areas of Troutdale Formation to the southeast of the Cascade Range also comprise fine-to-coarse grained fluvial sediments of Cascade Range provenance (Trimble, 1963; Leidos, 2018).

1.5.2 Hydrogeology

PANG Base Enclave is situated in an area that overlies significant hydrogeologic units, several of which are part of a regional aquifer system that serves as the city of Portland's supplemental water supply (Leidos, 2018). These hydrogeological units include (ascending order) the Sand and Gravel Aquifer, Confining Unit 1, Troutdale Sandstone Aquifer, Confining Unit 2, Troutdale Gravel Aquifer, Columbia River Sand Aquifer (CRSA), and the Overbank Deposits (Oregon Geo, 2009; Leidos, 2018).

Groundwater at the facility, the surrounding ORANG property, and PDX has been encountered at depths ranging from 2 to 10 feet below ground surface (bgs) within the shallow alluvial terrace deposits. Groundwater flow direction has considerable variation locally and between water-bearing units. It tends to fluctuate seasonally and in response to water level stage in the Columbia River caused by releases of the Bonneville Dam. For example, in the Overbank Deposits flow direction is toward the west and northwest, while measurements from the CRSA suggest flow direction fluctuates between northeast and south (Leidos, 2018). Shallow groundwater is

controlled by surface water features, including ditches, stormwater lines, and the Columbia River. Groundwater elevations beneath the adjacent airport suggest a hydraulic gradient toward the storm sewers (APEX, 2017).

Infiltration from snowmelt and precipitation are the main sources of recharge for the shallow aquifers (USGS, 1964). The majority of recharge to the aquifers occurs in the winter months, where precipitation and snowmelt are high, and evapotranspiration is low. The summer months are characterized by low precipitation, high runoff due to urbanization, and high evapotranspiration (USGS, 1998). This can be seen in the aquifers, with the highest water table in the winter and lowest water table in the summer and fall. Multiple drainage ditches throughout PDX as well as the Columbia Slough to the south also have an influence on water levels in the shallow zone.

Wells around PDX are approximately 17 feet bgs in the shallow unconfined aquifer. Groundwater in the unconfined aquifer is not a potable source for water (APEX, 2017). Depth to groundwater in these wells ranged from 2.51 to 10.65 feet bgs. Drinking water at the PANG Base Enclave is provided by the City of Portland, which has two main drinking water sources: the Bull Run Watershed and the Columbia South Shore Well Field (**Figure 1-2**). A quarter of Oregon's population relies on the Bull Run Watershed for clean drinking water, a protected surface water supply located within Mt. Hoot National Forest, 26 miles southeast of Portland (Portland Water Bureau, 2018).

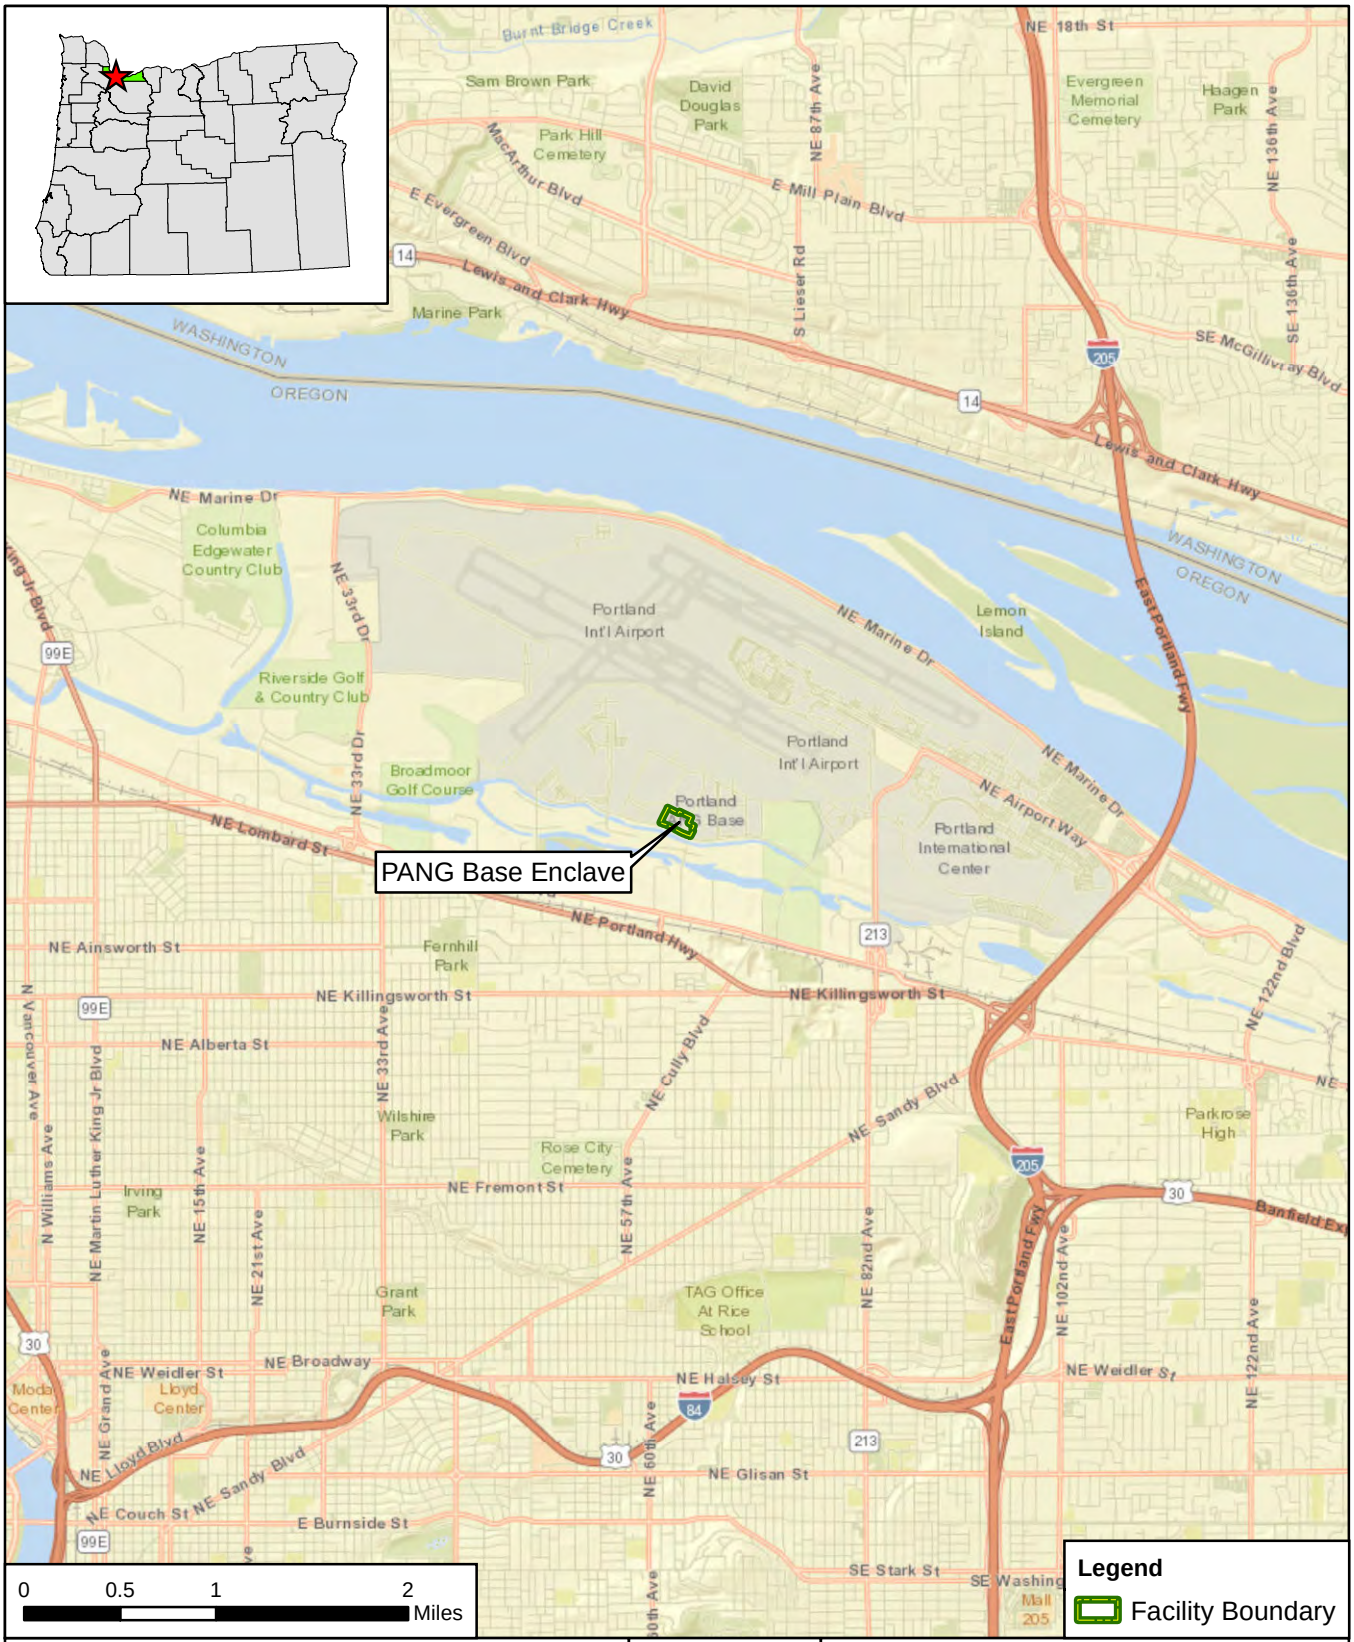
The remainder of drinking water for the City of Portland comes from the Columbia South Shore Well Field, comprised of 26 active wells located in three different aquifers less than one mile from the PANG Base Enclave. This well field is the second largest drinking water source in the state of Oregon and can produce 95 million gallons of water per day. When the Bull Run system is undergoing routine maintenance, during high turbidity events, emergencies, or when Portland needs an additional summer water supply, this well field is utilized to supply drinking water to the City of Portland (Portland Water Bureau, 2018).

1.5.3 Hydrology

PANG Base Enclave is a part of the Columbia Slough watershed, which is part of the much larger Columbia River Basin watershed. Although there are natural and significant water bodies and both navigable and non-navigable waterways at and adjacent to PANG Base Enclave, surface water flow eventually drains to the Columbia Slough, roughly 0.5 miles directly south of the facility (USGS, 1998; PANG, 2018). The Columbia Slough has nearly 18 miles of drainage within the southern floodplain of the Columbia River and receives water from springs to the northeast of PDX, local groundwater seepage from shallow saturated zone, as well as local surface runoff from PANG Base Enclave.

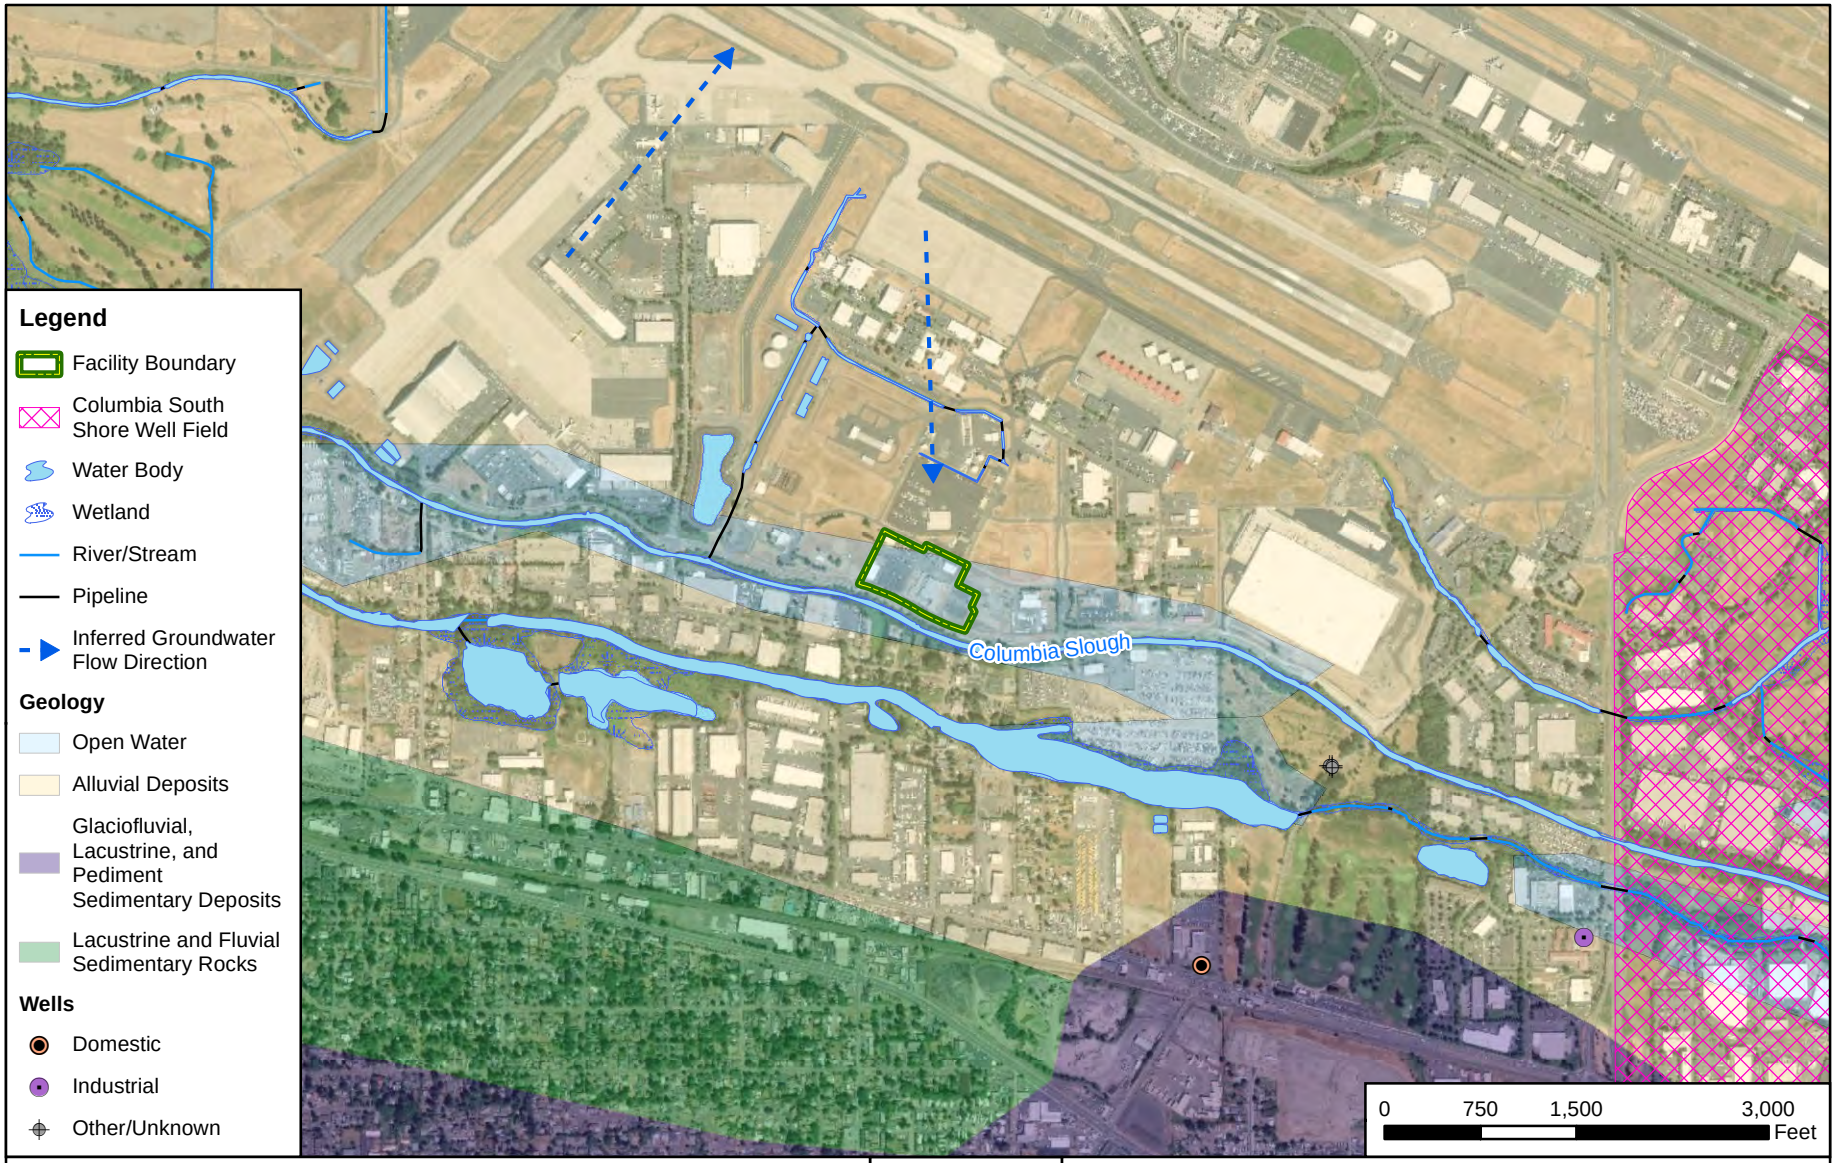
PANG Base has a man-made surface drainage system that dictates surface water flow in and around the base. Drainage ditches throughout the property, consisting of a main branch and a north branch and occupying roughly 1.8 acres, capture stormwater which is then directed to two man-made stormwater detention ponds located to the southwest of PANG Base. The main branch is approximately 2,800 feet long, while the north branch is roughly 1,700 feet long. They converge at a point of discharge to the detention ponds (PANG, 2018). Stormwater is discharged from these two detention ponds to the Columbia Slough (**Figure 1-3**).

1.5.4 Climate



PANG Base Enclave is situated in the northern edge of the Willamette Valley physiographic province, in a topographic boundary called the Columbia Plateau. The region extends northward into Washington State and is bound by the Coast Ranges to the west, the Cascade Range to the east, and the Columbia River to the northeast. The facility is in a temperate climate region with

mild winters and summers. The area is subject to low-volume, high-frequency rainfall events in the early spring and fall. The average annual temperature of Multnomah County is 53.6°F. Air temperatures in January and July average 38°-50° Fahrenheit (F) and 53°-77°F, respectively (NOAA, 2017).



Rainfall in the portion of the Willamette Valley physiographic province in which the facility is located averages approximately 45.59 inches per year, with nearly 105 days of 0.1 in of rain/precipitation or more. The average annual snowfall for the area is around 2.80 in, with most precipitation being rain during the winter months (NOAA, 2017). The average annual wind speed is 14.86 miles per hour and is usually out of the west and northwest (NOAA, 2017).

1.5.5 Current and Future Land Use

PANG Base Enclave was previously designated as an Air National Guard air base until transfer to ARNG. The facility is used primarily for storage of supplies, vehicles, and ammunition. No formal trainings occur at this facility and there have been no previous fire training areas or emergency response incidents at this facility since ORARNG came under control. The current lease agreement is set to expire in 2029; future land use is not anticipated to change during this time.

2. Fire Training Areas

No FTAs were identified within the PANG Base Enclave during the PA through interviews (**Appendix B**), historical document review, or Environmental Data Resource Reports. PANG Base Enclave facility personnel currently conduct any firefighting training activities at either Camp Adair in Corvallis or Camp Rilea near Warrenton, Oregon.

3. Non-Fire Training Areas

No non-FTAs were identified at PANG Base Enclave. During the PA, interviewees indicated that AFFF was not used, stored and/or released at the facility (**Appendix B**). Additionally, no fire suppression systems are present within any facility building.

4. Emergency Response Areas

No emergency response areas or incidents were identified within the PANG Base Enclave during the PA through interviews (**Appendix B**), historical document review, or Environmental Data Resource Reports. The City of Portland or Portland International Airport responses to all emergency incidents involving structural fires.

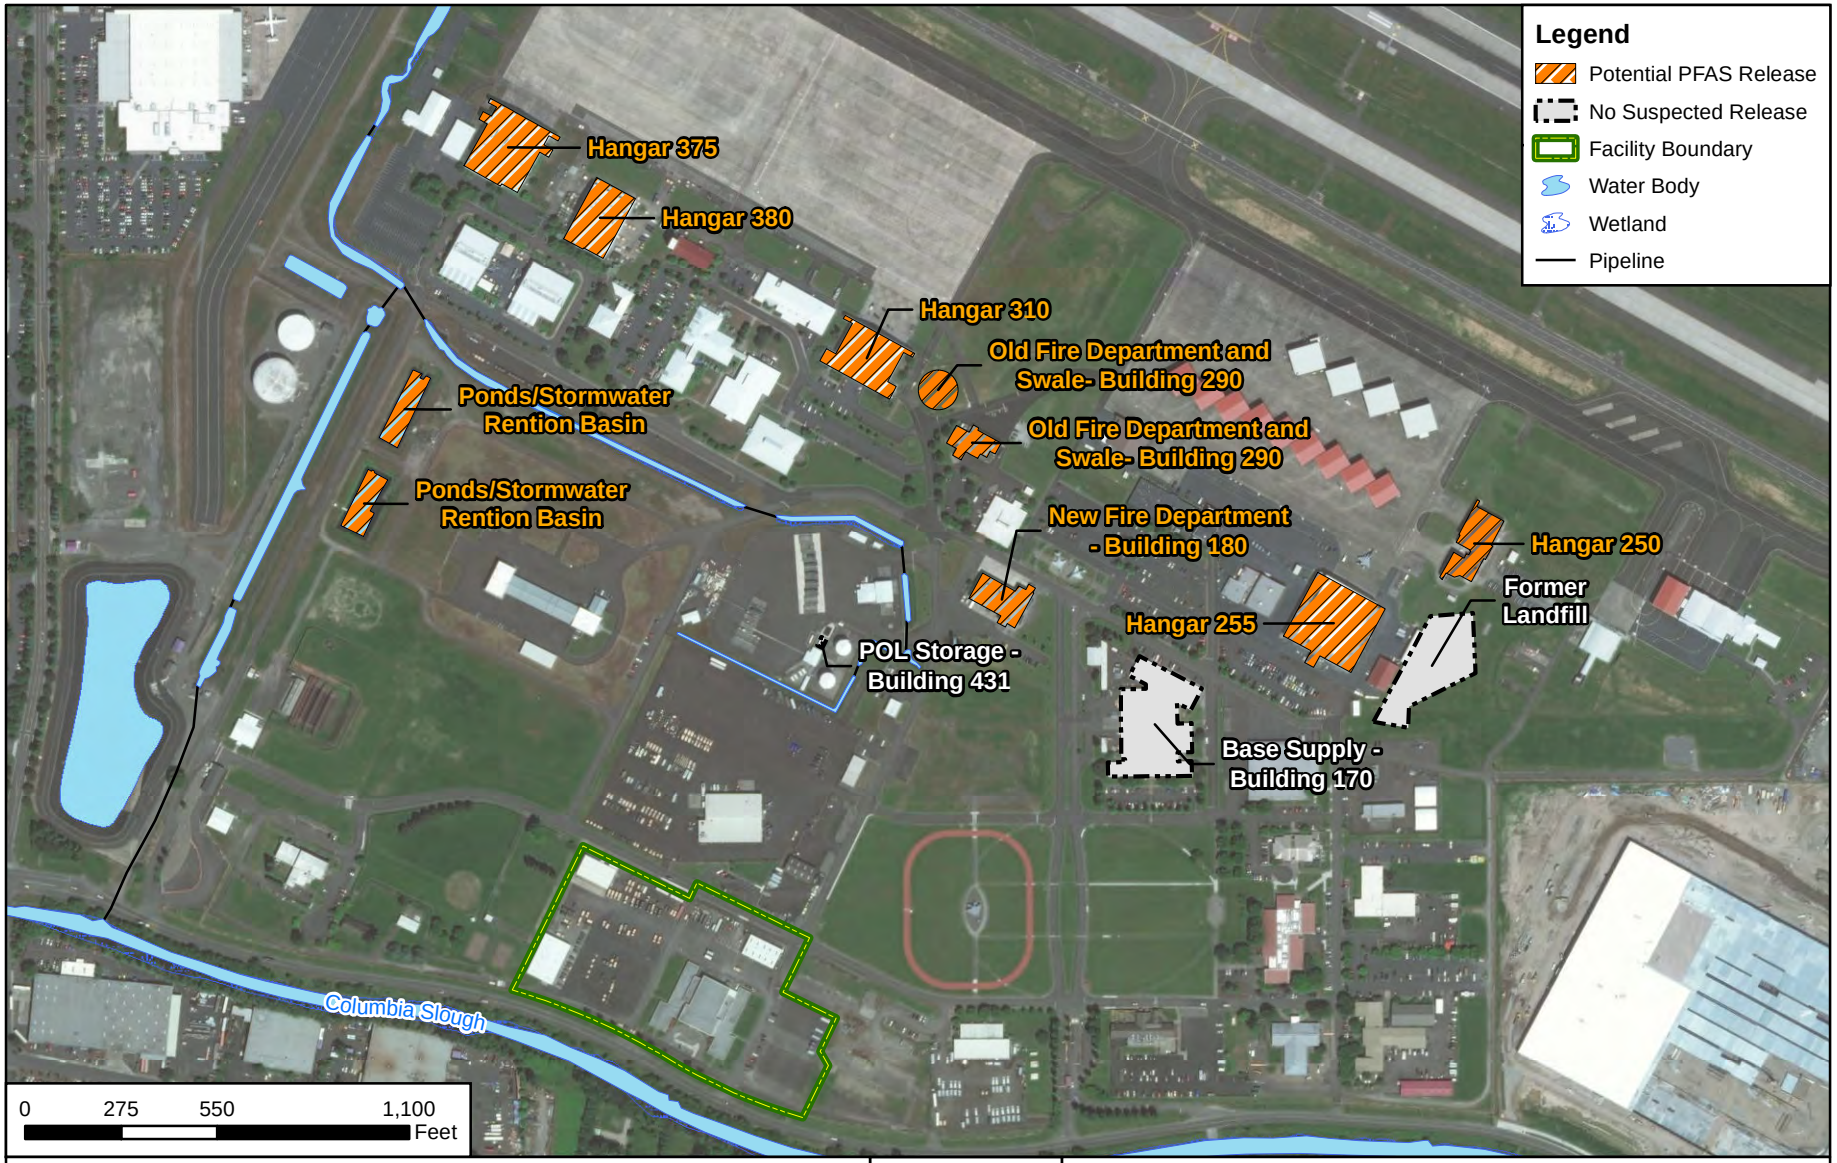
5. Adjacent Off-Facility Sources

Several potential off-facility sources of PFAS adjacent to the PANG Base Enclave, not under the control of the ARNG, were identified during the PA. Based on interviews with ORARNG personnel (**Appendix B**) and historical document review, all identified adjacent areas with potential AFFF releases are within the PANG Base boundaries. Descriptions of the adjacent sources are presented below and are shown on **Figure 5-1**.

5.1 Air National Guard Property

According to a PA conducted by engineering firm BB&E in 2016 and Apex in 2017, several potential areas of potential use, storage, or release of AFFF have historically occurred the PANG Base (BB&E, 2016). These locations are described below.

- Base Supply (Building 170): During the PA, twenty-seven 55-gallon drums of AFFF were located within the building, with historic storage occurring at the building since at least 2006. No spills or releases have been reported from these drums.
- New Fire Department (Building 180): Several firetrucks containing various quantities of AFFF, totaling approximately 550 gallons, as well as a 2,000-gallon foam trailer, are located within Building 170. Minor spills were reported to have occurred during filling of these vehicles over the years. Additionally, at least three documented occurrences of AFFF being discharged to the stormwater sewer occurred at this location.
- Hangar 250: This building contains a 200-gallon tank for fire suppression equipment; however, during the PA only 55 gallons were present in the tank. The fire suppression system is no longer present in the hangar; however, minor spills were reported from this system in the tank storage room prior to the removal of the system. One empty 55-gallon barrel was still present in the Hangar during the PA.
- Hangar 255: A 600-gallon AFFF fire suppression system is located within the mechanical room of this hangar, with known minor leaks occurring into the main hangar. Approximately one-half gallon of concentrated AFFF was released in 2005 as part of a fire suppression system test, with all residual flowing onto the asphalt and then rinsed down the storm drain outside the hangar. Several days after the test, the stormwater ditch that collects residual from the storm drain showed evidence of foam.
- Old Fire Department (Building 290) and Swale: Historic storage of AFFF-capable fire and crash response vehicles occurred at this building from approximately 1986 to 2005. Fire department personnel indicated minor spills occurred during filling of the AFFF tanks on the vehicles and minor leaks occurred from the equipment. Additionally, an undocumented spill historically occurred that discharged an unknown quantity of AFFF into the drainage swale northwest of the building.
- Hangar 310: This building has AFFF fire suppression equipment stored in the mechanical room of this hangar. It is estimated that two 800-gallon tanks and one 600-gallon tank are stored in this room, with minor spills historically occurring which then release into the main hangar. It is presumed that unintended spills from these tanks were hosed off into the hangar floor drains which connect to the sanitary sewer. It is likely some AFFF flowed onto the ramp just north of this hangar, which is connected to the storm water system.
- Hangar 380: Historically, AFFF fire suppression equipment was stored in the mechanical room of this hangar; however, all tanks were removed in 2005. While there are no known leaks or spills from these tanks, given the prior releases of AFFF tanks in other on-site hangars, there is the potential for unintended spills or releases to have occurred from these tanks.



- Hangar 375: There is currently AFFF fire suppression equipment stored within the mechanical room of this hangar. It is estimated that two 800-gallon tanks and one 600-gallon tank are stored in this room, with minor spills historically occurring which then release into the main hangar. It is presumed that unintended spills from these tanks were hosed off into the hangar floor drains which connect to the sanitary sewer. It is likely some AFFF flowed onto the ramp just north of this hangar, which is connected to the storm water system.
- POL Storage (Building 431): Historically, this building contained an AFFF fire suppression system for the fuel tanks located within this building. No spills, leaks, or releases were reported from the AFFF system during its installation and the fire suppression system was removed in 2013.
- Ponds/Stormwater Retention Basins: Two man-made ponds are located on the west-central portion of the base, collectively receiving approximately 95% of PANG Bases' stormwater discharge. Any actual or potential releases mentioned above that discharged into the base stormwater sewer system likely flowed into these two ponds.

Based on the proximity of these locations to ORARNG property as well as fluctuation in groundwater flow direction, there is the potential for AFFF releases from ORANG property to impact the PANG Base Enclave. Surface water flow is directed by a man-made surface drainage system that encompasses the entire PANG Base and the Enclave, and generally discharges to the north towards the Columbia River.

5.2 Landfills

An abandoned, buried landfill is located on property previously leased to the ORANG by the Port of Portland until 1986. This landfill covers approximately one acre of land and is located east of Hangar 255, described above in **Section 5.1**. This landfill was used by both ANG and the ARNG from 1949 until 1956, and consist mostly of old paint cans, oil residue, batteries, paper waste, and broken equipment parts (OTC, 1996).

Landfills are not usually a primary release area of PFAS, but materials disposed in landfills may create a secondary source of contamination. Such materials may include used AFFF storage containers or products associated with waterproofing uniforms or boots. Given the timeframe of use for this landfill preceded manufacturing of AFFF, it is unlikely any PFAS containing materials were disposed of in this landfill.

Figure 5-1

Q:\Projects\ENV\GEARS\GEO\MAES 2012 Unrestricted\Fort Meade\E. Data Management\GIS\MXDs\Chisholm_6th\March2017\ Fig_5-1_PANG_Base_Enclave_Adjacent_Sources.mxd

6. Conceptual Site Model

Based on the PA findings from interviews with facility personnel, on-facility observations, review of Environmental Data Resource reports, and online research, no release areas were identified as AOIs at the PANG Base Enclave. A conceptual site model (CSM) identifies three components necessary for potentially complete exposure pathways related to a site: (1) source, (2) pathway, and (3) receptor. If any of these elements are missing, the pathway is considered incomplete. However, since no PFAS sources were identified to originate at the PANG Base Enclave or from activities associated with the facility, CSMs were not developed.

Nearby off-facility sources were identified during this PA. According to an EDR Radius Map™ Report run in 2015 of the adjacent Air National Guard Base, there are 153 water wells within a one-mile radius of the Base, none of which were listed as potable wells (BB&E, 2016). However, a well field used as a supplemental water supply for the City of Portland is located 0.75 miles southeast of the facility (BB&E, 2016). Based on actual and potential AFFF releases at the nearby ORANG facility as well as fluctuating groundwater and surface water flow directions, there is the potential for adjacent AFFF releases to impact groundwater and surface water at the PANG Base Enclave.

7. Conclusions

This report presents a summary of available information gathered during the PA on the potential use, storage, or release of AFFF and other PFAS-related activities at PANG Base Enclave. The PA findings are based on the information presented in **Appendix A** and **Appendix B**.

7.1 Findings

Based on information obtained during interviews conducted with facility personnel, facility observations, and reviewed documentation, it is confirmed that AFFF has never been stored, used, or released at the PANG Base Enclave; therefore, no AOIs related to PFAS releases were identified.

Interviewee knowledge from ORARNG personnel at PANG Base Enclave dates back to at least 2004. Evidence obtained during the PA supports that current or former ARNG facility activities have not contributed to any potential PFAS contamination in soil, groundwater, surface water, or sediment. No potential areas of PFAS use, release, or storage, current or historical, were identified at the PANG Base Enclave.

However, there are several potential PFAS sources adjacent to the facility (**Figure 7-1**). Based on fluctuating water flow patterns and the close proximity of groundwater wells and a well field, the reported releases within ORANG property (**Section 5.1**) have the potential to impact groundwater and surface water at the PANG Base Enclave.

7.2 Uncertainties

A number of information sources were investigated during this PA to determine the potential for PFAS-containing materials to have been stored, used, or released at the facility. Historically, documentation of PFAS use was not required because PFAS were considered benign. Therefore, records were not typically kept by the facility or available during the PA on the disposition and use of PFAS in training, firefighting, or other non-traditional activities.

The conclusions of this PA are predominantly based on the information provided during interviews with personnel who had direct knowledge of PFAS use at the facility. Sometimes the provided information was vague or conflicted with other sources. Gathered information has a degree of uncertainty due to the absence of written documentation, the limited number of personnel with direct knowledge due to staffing changes, the time passed since PFAS was first used (1969 to present), and a reliance on personal recollection. Inaccuracies may arise in potential PFAS release locations, dates of release, volume of releases, and the concentration of AFFF used. There is also a possibility the PA has missed a source of PFAS, as the science of how PFAS may enter the environment continually evolves.

In order to minimize the level of uncertainty, readily available data regarding the use and storage of PFAS were reviewed, current personnel were interviewed, multiple persons were interviewed for the same potential source area, and potential source areas were visually inspected. The uncertainties associated with the PA are summarized in **Table 7-1**.

Table 7-1: Uncertainties

Area	Source of Uncertainty
PANG Base Enclave	Direct interviewee knowledge is not available before 2004. Whether potential use, storage, or release of PFAS-containing materials occurred at this facility prior to 2004 is unknown. Function and use of the facility relating to military operations has not changed since the facility was constructed in the 1940s.

7.3 Potential Future Actions

Based on the documented absence (2004-present) of the use, storage, or release of PFAS-containing materials at PANG Base Enclave, no AOIs were identified during the PA. Evidence does not indicate that current or former ARNG activities contributed PFAS contamination to soil, groundwater, surface water, or sediment at the facility or adjacent areas. PANG Base Enclave will not move forward in the CERCLA process.

BOOK 2067 PAGE 133

THIS INDENTURE made this 15th day of June, 1961, between THE PORT OF PORTLAND, a municipal corporation of the State of Oregon, grantor, and the STATE OF OREGON, grantee, witnesseth:

WHEREAS, the grantor is the owner of the hereinafter described property located in Sections 17 and 18, Township 1 North, Range 2 East, Willamette Meridian, Multnomah County, Oregon, and

WHEREAS, the grantee desires to acquire said property for use and to continue to be used for a public purpose, namely that of constructing, maintaining and operating an Oregon National Guard Armory thereon, and

WHEREAS, pursuant to ORS 271.330 (1) the grantor has determined that the hereinafter described property is not needed for its public use; now, therefore, this indenture

W I T N E S S E T H

That THE PORT OF PORTLAND, a municipal corporation of the State of Oregon, in consideration of the premises and of the sum of One Dollar ($1.00) has granted, bargained, sold and conveyed and by these presents does grant, bargain, sell and convey unto the STATE OF OREGON on condition that it is used forever as a site for the construction, maintenance and operation of an Oregon National Guard Armory all of the right, title and interest of THE PORT OF PORTLAND in and to the following described real property situated in Sections 17 and 18, Township 1 North, Range 2 East of the Willamette Meridian, Multnomah County, Oregon bounded and described as follows, to wit:

Commencing at a point that bears South 272.91 feet and East 1052.55 feet from the northeast corner of the Wm. Hall D.L.C., and running thence South 2423.35 feet to a point which is 45 feet North from the center line of Northeast Cornfoot

Road; thence along a line parallel to and 45 feet northerly from the center line of said Cornfoot Road, as follows: Along the arc of a curve to the left with a radius of 1228.30 feet (Tangent bearing S 89° 53' E) a distance of 199.75 feet to a point; thence North 80° 30' East 248.29 feet to a point; thence around the arc of a curve to the right with a radius of 545.00 feet a distance of 506.99 feet to a point; thence South 46° 12' East a distance of 95.36 feet to a point; thence around the arc of a curve to the left with a radius of 355.00 feet a distance of 233.07 feet to a point; thence South 82° 49' East a distance of 176.80 feet to a point; thence around the arc of a curve to the right with a radius of 645.00 feet a distance of 164.05 feet to a point; thence South 68° 18' East a distance of 328.50 feet to a point; thence South 76° 08' East a distance of 289.58 feet to a point; thence South 82° 05' East a distance of 301.29 feet to a point; thence around the arc of a curve to the right with a radius of 1845.00 feet a distance of 613.09 feet to the true place of beginning; running thence North 26° 19' East a distance of 483.62 feet along the westerly side of "G" Street to a point; thence South 63° 41' East a distance of 358.00 feet along the northerly side of 3rd Street to a point; thence South 26° 19' West a distance of 497.32 feet along the easterly side of "H" Street to a point, said point being 45 feet northeasterly from the center line of Northeast Cornfoot Road; thence northwesterly along the arc of a curve to the right with a radius of 1592.10 feet a distance of 204.96 feet to a point; thence North 58° 38' West a distance of 11.06 feet to a point; thence around the arc of a curve to the left with a radius of 1845 feet a distance of 143.63 feet to the true place of beginning; containing 4.03 acres more or less,

subject, however, to the following exceptions, reservations, and conditions:

1. There is hereby reserved to the grantor, its successors and assigns, for the use and benefit of the public, a right of flight for the passage of aircraft in the air space above the surface of the premises herein conveyed, together with the right to cause in said air space such noise as may be inherent in the operation of aircraft, now known or hereafter used for navigation of or flight in the air, using said air space or landing at, taking off from or operating on Portland International Airport.

2. The grantee by accepting this conveyance expressly agrees that it will not erect nor permit the erection of any structure or object nor par-

mit the growth of any tree on the land conveyed hereunder above a mean sea level elevation of 93 feet. In the event the aforesaid covenant is breached the grantor reserves the right to enter on the land conveyed hereunder and to remove the offending structure or object and to cut the offending tree, all of which shall be at the expense of the grantee.

3. The grantee by accepting this conveyance expressly agrees that it will not make use of the said property in any manner which might interfere with the landing and taking off of aircraft from said Portland International Airport or otherwise constitute an airport hazard. In the event the aforesaid covenant is breached the grantor reserves the right to enter on the land conveyed hereunder and cause the abatement of such interference at the expense of the grantee.

PROVIDED HOWEVER, and it is one of the considerations for this conveyance and an express condition hereof that:

1. In the event said hereinabove described premises shall at any time cease to be used for the public purposes hereinabove set forth, namely the construction, maintenance and operation of an Oregon National Guard Armory, THE PORT OF PORTLAND or its successors may re-enter upon said premises and the title, right of possession and all other rights transferred by this indenture to the STATE OF OREGON shall revert to THE PORT OF PORTLAND. In the event THE PORT OF PORTLAND, acting pursuant to this condition, re-enters upon and regains possession of said premises, the STATE OF OREGON shall have the right to remove or cause to be removed within sixty (60) days following an act of re-entry by THE PORT OF PORTLAND all buildings and improvements placed upon said premises by the STATE OF OREGON.

TO HAVE AND TO HOLD the said granted premises unto the STATE OF OREGON subject to the exceptions, reservations and conditions hereinabove set forth.

IN WITNESS WHEREOF, THE PORT OF PORTLAND, grantor, pursuant to a resolution of its Board of Commissioners, duly and legally adopted, has caused these presents to be signed by its President and Assistant Secretary and its corporate seal to be affixed this 15th day of June 1961.

THE PORT OF PORTLAND

EXECUTIVE SUMMARY

A. INTRODUCTION

The Hazardous Materials Technical Center (HMTC) was retained in July 1986 to conduct the Installation Restoration Program (IRP) Phase I - Records Search of the 142nd Fighter Interceptor Group (FIG), Portland International Airport (ANG) Portland, Oregon (hereinafter referred to as Portland ANGB) and the 104th Tactical Control Flight (TCF), North Bend Air National Guard Station (North Bend, Oregon (hereinafter referred to as North Bend ANGS), under Contract No. DLA-900-82-C-4426 Records Search. The Records Search included:

- an onsite visit, including interviews with 19 Base employees at the Portland ANGB and North Bend ANGS conducted by HMTC personnel during 7-10 July 1986;
- the acquisition and analysis of pertinent information and records on hazardous materials use and hazardous waste generation and disposal at Portland ANGB and North Bend ANGS;
- the acquisition and analysis of available geologic, hydrologic, meteorologic, and environmental data from pertinent Federal, State and local agencies; and
- the identification of sites which may be potentially contaminated with hazardous waste/hazardous materials (HW/HM) at Portland ANGB and North Bend ANGS.

B. MAJOR FINDINGS

The major operations of the 142nd FIG that have produced hazardous waste include aerospace ground equipment (AGE) maintenance, ground vehicle maintenance, petroleum oil and lubricant (POL) management, and aircraft maintenance. These operations generate varying quantities of waste oils, recovered fuels, spent cleaners, and solvents.

The HW/HM generated by these operations are being disposed of through: the Defense Reutilization and Marketing Office (DRMO) and/or contract disposal for recycling. Previously the Air Force disposed of the waste by burning at the Burn Pit Area.

Interviews with 19 personnel and a field survey resulted in the identification of eight potentially contaminated disposal and/or spill sites at Portland ANGB and seven potentially contaminated sites at the North Bend ANGS. Six of the 15 sites were evaluated and prioritized using the Air Force Hazard Assessment Rating Methodology (HARM) because potential for contaminant migration exists at these sites.

- o Site No. 1 - Central Hazardous Waste Storage Area
- o Site No. 2 - Civil Engineering Hazardous Material Storage Area
- o Site No. 3 - Hush House Area
- o Site No. 4 - Main Drainage Ditch
- o Site No. 5 - AGE Maintenance Shop
- o Site No. 7 - Burn Pit Area

C. CONCLUSIONS

The six HM/HW sites identified as potentially contaminated are Site Nos. 1, 2, 3, 4, 5, and 7. These sites have been further evaluated and given a Hazard Assessment Score (HAS), using the Air Force Hazard Assessment Rating Methodology (HARM).

Site No. 1 - Central Hazardous Waste Storage Area

This storage area was temporarily used for storing 55-gallon drums containing waste oil, solvents, fuels, PD-680, DF-2, shop waste, transformers, and capacitors. During the site visit, discolored gravel and soil were observed; however, no spills have occurred at this site.

Site No. 2 - Civil Engineering Hazardous Material Storage Area

Fifty-five-gallon drums of methyl ethyl ketone are stored in a horizontal position at this site. Although no spills have occurred here, discolored gravel was observed during the site visit.

Site No. 3 - Hush House Area

Discolored soil and grass were noted during the site visit, possibly from effluent from the oil/water separator and holding tank.

Site No. 4 - Main Drainage Ditch

JP-4, AVGAS, diesel fuel, and unknown waste, which have been spilled on runways, aprons, and other paved areas, are channeled to this site. The Base drainage system discharges offbase, but is activated only during precipitation, so spills and releases tend to accumulate in the immediate areas.

Site No. 5 - AGE Maintenance Shop

This site is an area adjacent to Building 1225 where batteries were drained directly onto the soil. Buckets of oil and solvent were also dumped in this area. Discolored soil, gravel, and stressed vegetation were observed during the site visit.

Site No. 7 - Burn Pit Area

This area served as a fire training area where JP-4 and other flammables were ignited. Several thousand gallons per year were used here between 1957 and 1978.

D. RECOMMENDATIONS

Because of the potential for contamination migration at Portland ANGB, initial stages of the Phase II/IVA program are recommended for six of the fifteen potentially contaminated sites. This program should consist of analysis of soil and/or groundwater for priority pollutants, heavy metals, organics, oil and grease, and other hydrocarbons. The primary purposes of investigating the proposed locations are the following:

- To determine whether pollutants are present at each site or determine that no pollutants are present; and
- To determine whether groundwater at each site has been contaminated, and if it has, give quantification with respect to contaminant concentrations, the boundary of the contaminant plume, and the rate of migration.

I. INTRODUCTION

A. Background

The 142nd Fighter Interceptor Group (FIG) is presently located at the Portland International Airport. After World War II, most of the area which is now the Portland ANGB was converted to an Air National Guard Base. It then became an active Air Force Base in 1950; in 1964, it was again converted to an Air National Guard Base and has maintained this status to the present time. The 104th Tactical Control Flight (TCF) is located in North Bend, Oregon and has been active since June 1981. Past and present operations at both Air National Guard locations have involved the use and disposal of hazardous materials. Because of this, the Air National Guard has implemented its Installation Restoration Program (IRP). The IRP is a four-phase program as follows:

Phase I - Records Search (Installation Assessment) to identify and prioritize past disposal sites posing a potential and/or actual hazard to public health or the environment.

Phase II/IVA - Site Characterization/Remedial Action Plan to define and quantify, via field studies, the presence or absence of contamination that may have an adverse impact on public health or the environment, to develop a Remedial Action Plan (RAP), and if directed by Air National Guard Support Center (ANGSC), prepare designs and specifications.

Phase III - Technology Base Development (if needed) to develop new technology for accomplishment of remediation.

Phase IVB - to implement Site Remedial Action.

B. Purpose

The purpose of this IRP Phase I - Records Search (hereafter referred to as Records Search) is to search for, identify, and assess actual or potential contaminant migration at Portland ANGB and North Bend ANGS by reviewing available records and interviewing Base personnel who have a knowledge of present and past operations.

C. Scope

The scope of this Records Search is limited to spills, leaks, or disposal problems occurring on ANGB property of the 142nd FIG, Portland, Oregon, and the 104th TCF, North Bend, Oregon. Thus far, the following actions have been taken:

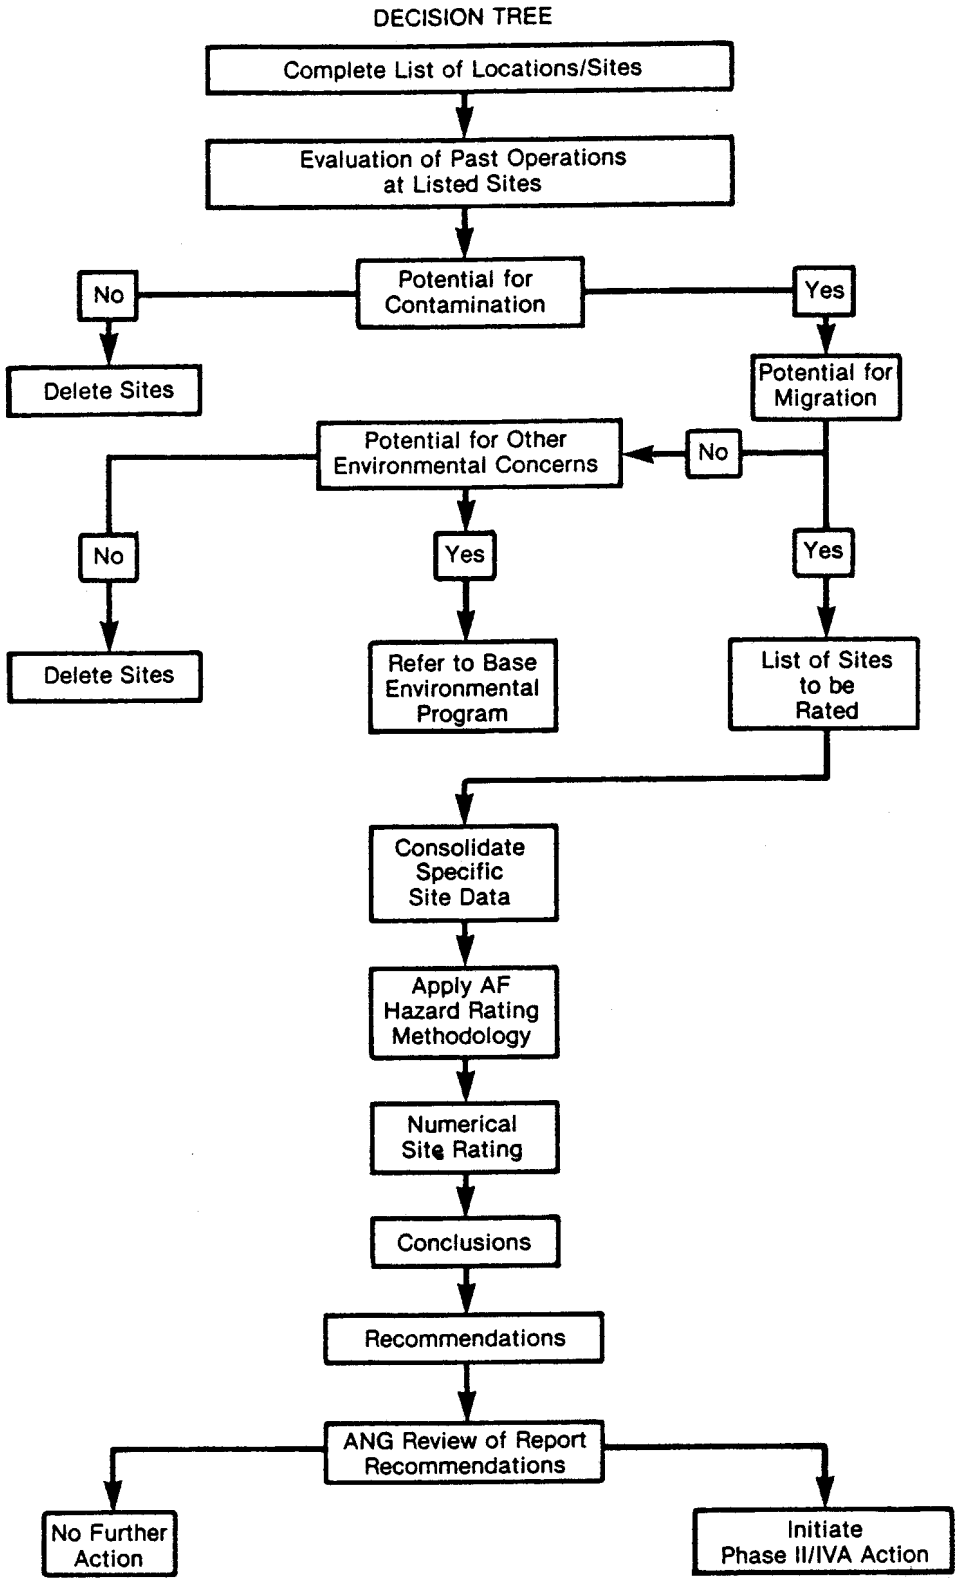
- o An onsite Portland ANGB and North Bend ANGS visit;
- o The acquisition of pertinent information and records of hazardous materials use and hazardous waste generation and disposal practices at the Portland ANGB and North Bend ANGS;
- o The acquisition of available geologic, hydrologic, meteorologic land use, and critical habitat data from various Federal and State agencies;
- o A review and analysis of all information obtained; and
- o The preparation of a report, to include recommendations for further actions.

The onsite visit took place during 7 - 10 July 1986. The following personnel were assigned to the team and provided input to this report:

- o Mr. Timothy Gardner, Environmental Scientist
- o Ms. Jody Mooney, Environmental Scientist
- o Ms. Natasha Brock, Environmental Scientist (not present for visit)

Resumes of the team members appear in Appendix E.

Individuals from the ANG who assisted in the Records Search were Lt. Col. Michael Washeleski, Bioenvironmental Engineer, ANGSC/SGB, and selected members of the 142nd FIG and the 104th TCF. The point of contact for Portland ANGB and North Bend ANGS was Capt. Alan Malone, Base Civil Engineer.



D. Methodology

Figure 1 is a flowchart of Records Search Methodology. HMTC identified eight potentially contaminated locations at Portland ANGB and seven at North Bend ANGS where hazardous materials were used and disposed of.

HMTC evaluated past and present operating procedures at the fifteen identified potentially contaminated hazardous waste disposal/spill sites to determine whether environmental contamination may have occurred. This evaluation was facilitated by extensive interviews with 19 Base employees familiar with the various operating areas of Portland ANGB and North Bend ANGS. Appendix A lists their principal areas of knowledge and their years of experience at the Base and Station.

Blueprints and records of Portland ANGB and North Bend ANGS were reviewed to supplement information obtained from the interviews. In addition, the team toured the identified sites to determine the presence of visible contamination and to assess the potential for contamination migration. Particular attention was given to locating nearby drainage ditches and surface water bodies. After analyzing the necessary environmental information, six of the 15 identified sites were given a Hazard Assessment Score (HAS) using the Air Force Hazardous Assessment Rating Methodology (HARM) because a potential for migration exists (Step 4 of Figure 1).

Figure 1.
Records Search Methodology Flow Chart.

II. INSTALLATION DESCRIPTION

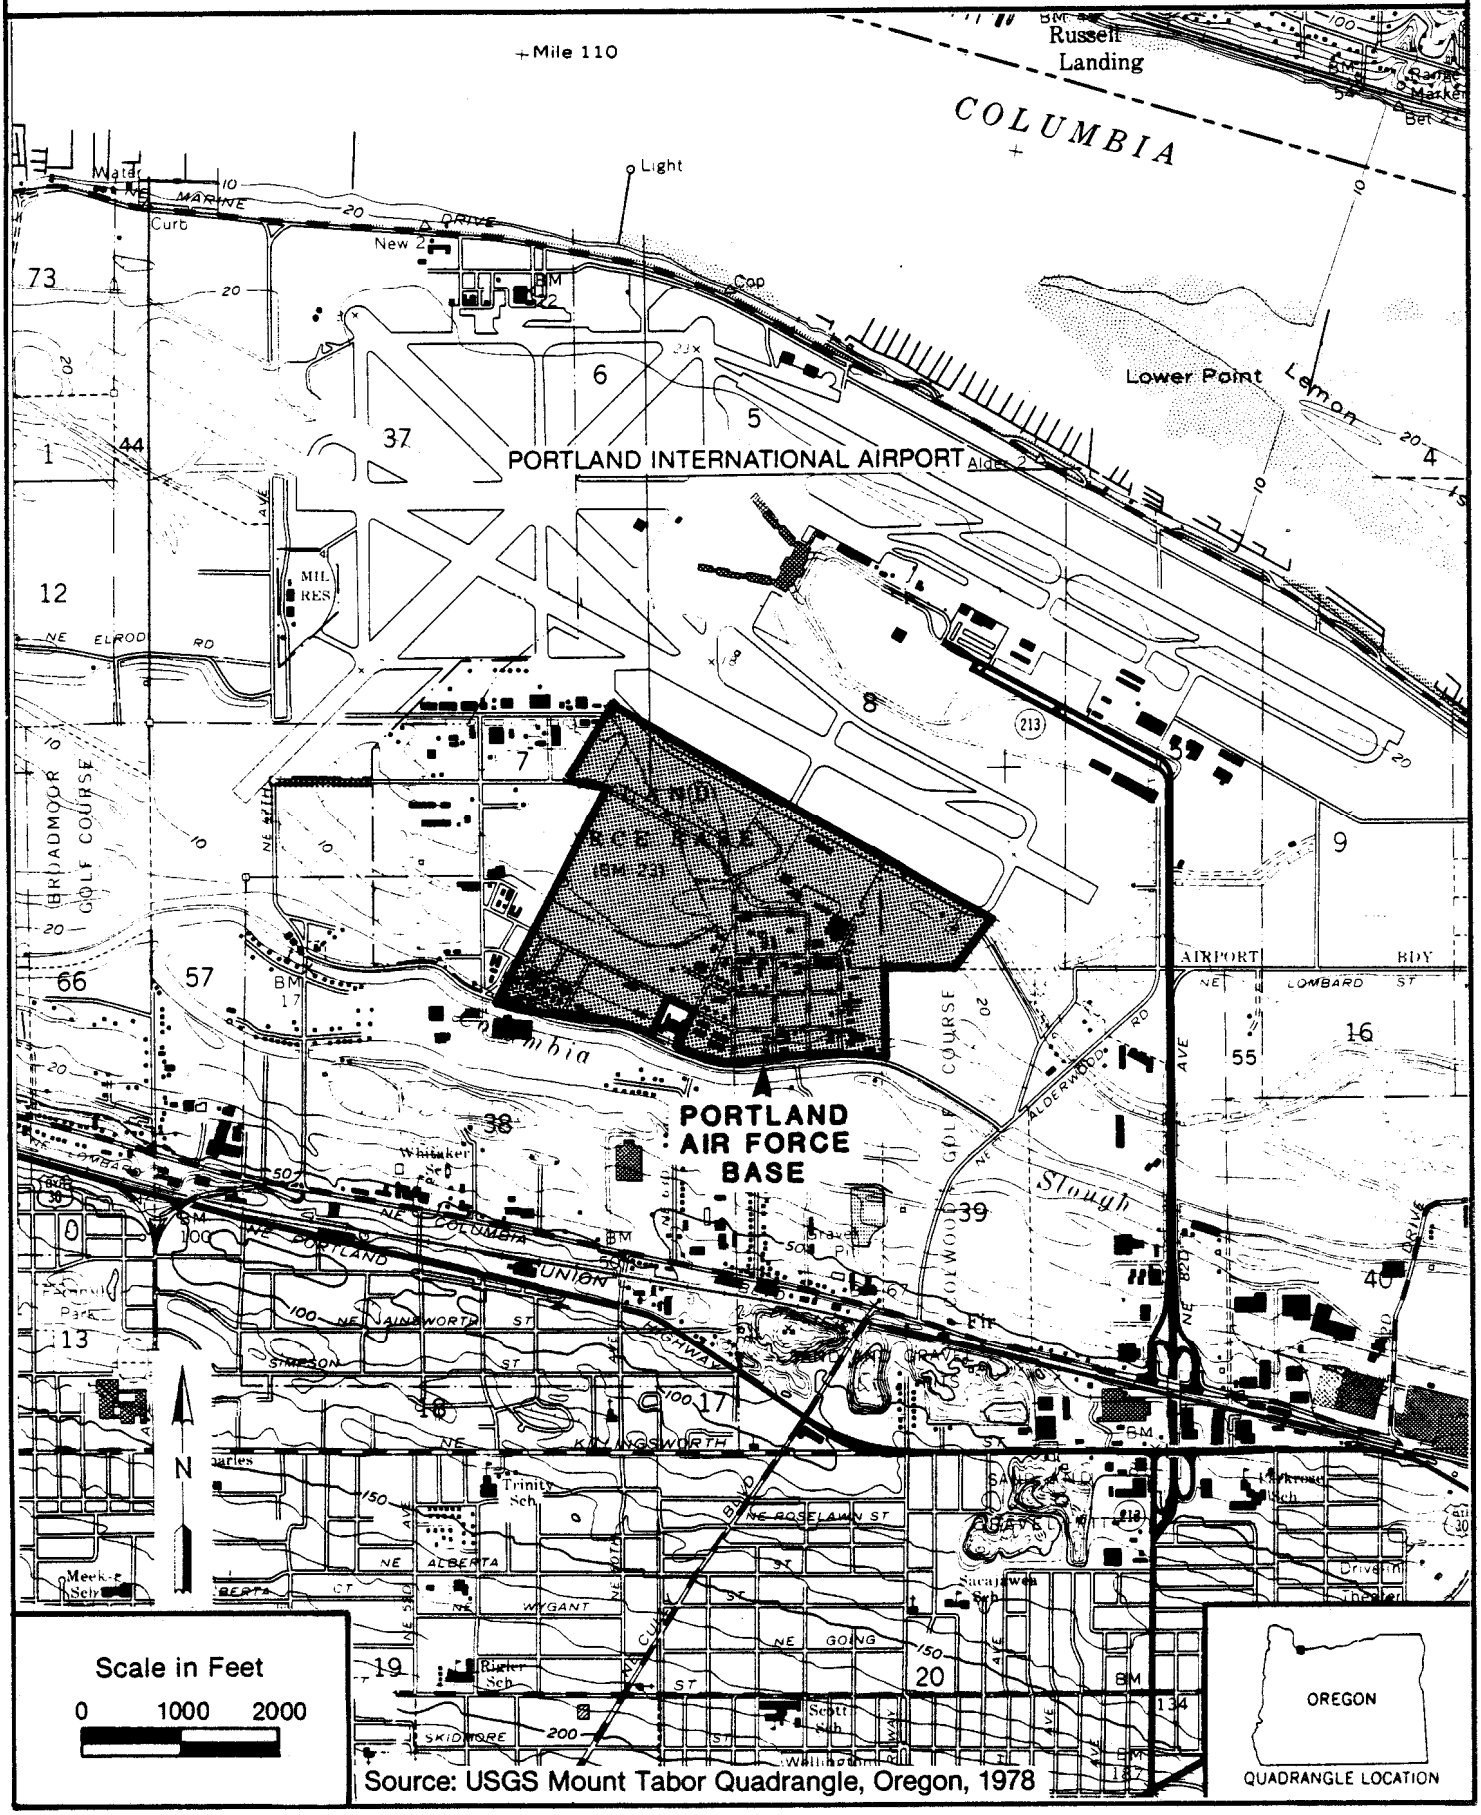
A. Location

The Portland ANGB is located on the south side of the Portland International Airport in Portland, Oregon (see Figure 2). The airport is located northeast of the city, situated between the Columbia River and Columbia Slough.

The North Bend ANGS is located approximately two miles south of Lakeside, Oregon and one and one half miles east of the town Saunders Lake, off State Route 101 (see Figure 2A). The Base is situated in an under-developed area near tributaries of Shutter Creek which feeds into Shutter Arm and Tenmile Lake.

B. Organization and History

Portland ANGB was opened in 1941 to 1945 as an Army Air Base. After World War II, most of the Base was converted to operation as an Air National Guard Base. It became an active Air Force Base in 1950 until 1964, when it once again became an Air National Guard Base and has maintained this status to the present time.



The mission of Portland ANGB is to provide Operational Headquarters and Training facilities for the 142nd Fighter Squadron, which is the Portland ANGB host unit. Several other units, including the 304th ARRS (Res), 40th AeroMed Squadron (Res), 83rd Aerial Port Squadron (Res), and the Oregon Army National Guard, also occupy the Portland ANGB and each has an individual military mission. While some of the units stationed at the Base provide peacetime support functions and services to the Base in general, the purpose of others is strictly related to training and readiness for their military mission.

The mission of North Bend ANGS is to provide a permanent Coastal Defense Radar Facility. The facility was maintained by the Air Force from the 1950s until 1980. The 104th Tactical Control Flight (TCF) received Federal recognition in June 1981 at Kingsley Field in Klamath Falls, Oregon. In June 1981,

HMTC

HMTC

Figure 2A.

Site Map of North Bend Air National Guard Station, North Bend, Oregon

Source: USGS Lakeside Quadrangle, Oregon, 1985

the 104th TCF relocated to North Bend AFS and reactivated the site as the North Bend ANGS.

III. ENVIRONMENTAL SETTING

A. Meteorology

Precipitation in Portland, Oregon averages 37.81 inches annually, and in North Bend, Oregon averages 60.00 inches annually. By calculating net precipitation according to the method outlined in the Federal Register (47 FR 31224, 16 July 1982), a net precipitation value of 13.81 inches per year is obtained for Portland and 36.00 inches per year is obtained for North Bend. Rainfall intensity based on 1-year, 24-hour rainfall for Portland is 2.0 inches and 3.0 inches for North Bend (calculated according to 47 FR 31235, 16 July 1982, Figure 8).

B. Geology

1. Regional

a. Portland ANGB

Multnomah County, Oregon, and the Portland area are situated on the topographic division known as the Columbia Plateau. During the latter part of the Eocene Epoch (36-57 million years ago), the Portland area was influenced by volcanic eruptions in the eastern part of the area. Fissure eruptions of flood basalt during the middle Miocene Epoch (5-24 million years ago) produced great plains of Columbia River Basalt east of the Portland area. During the late Miocene and early Pliocene Epochs (2-5 million years ago), weathering processes changed the exposed rocks partially to clay. As the basins were filled, or when the outlets had been breached to the level of the surface of the sedimentary accumulations, conditions were changed suddenly to an environment of stream deposition. The Columbia River brought its load of coarse gravel and sand of foreign origin through the Cascade Mountains and deposited it in the gradually subsiding basin. These gravel deposits of the early Pliocene Columbia River form an important part of the Troutdale Formation. The Post-Troutdale Pliocene Epoch was a time of renewed small-scale discontinuous volcanic activity.

b. North Bend ANGS

The bedrock in the North Bend ANGS area consists of Mesozoic basalts, turbidites, conglomerates, sandstones and siltstones, including the Rogue Formation, the Galice Formation, serpentinite and diorite intrusions, the Otter Point Formation, the Dothan Formation, the Riddle Formation, the Humbug Mountain Conglomerate, and the Days Creek Formation. The total thickness of these units is approximately ten miles. Overlying the Mesozoic Formations are Cenozoic (Eocene) turbidite sandstones and siltstones of the Roseburg Formation, the Looking-glass Formation, the Fluornoy Formation, the Tyce Formation, and the Elkton Formation. Overlying these units are the Bateman, Colorado, Bastendorf, and Tunnel Point Formations of the late Eocene to early Oligocene Epochs. These are overlain by unnamed Miocene beds, the Pliocene Empire Formation, the Pleistocene Coquille Formation, and marine and river terrace deposits. The surficial deposits consist of alluvium.

2. Local

a. Portland ANGB

The Portland ANGB is located on a levee-protected flood plain of the Columbia River. Typically, the Recent alluvial subsurface materials of the flood plain consist of bedded sands, silts and clays. Studies have indicated that these fine-grained materials range in thickness from 100 to 200 feet. Underlying the finer-grained deposits are Pleistocene gravels and/or Pliocene gravels of the Troutdale Formation.

The soils at Portland ANGB are represented by two soil series. The Pilchuck Soil Complex accounts for almost all the soils found at Portland, while the Sauvie-Rafton Complex accounts for a small area at the south-southwest corner of the Portland ANGB. Undisturbed Pilchuck Soils consist of several soil layers: the surface layer is very dark grayish-brown sand about 12 inches thick. The underlying layer is dark brown sand to a depth of 60 inches or more. About 35 percent of this complex is sandy material 20 feet or more in

depth. This material has been dredged and deposited over Moag, Rafton, and Sauvie Soils and in some areas it has been used to fill small swamps. In most areas the fill has raised the surface to an elevation above the annual flood plain. Permeability of the Pilchuck Soil is rapid. The Sauvie-Rafton Complex consists of very deep, poorly drained Sauvie Soils and very poorly drained Rafton Soils. These soils occur on the broad flood plains along the Columbia River. The surface layer is very dark grayish-brown silt loam about 15 inches thick. The subsoil, a dark grayish-brown silty clay loam, is mottled and is about 24 inches thick. The substratum is dark grayish-brown, mottled, very fine sandy loam to a depth of 60 inches or more. Permeability rates for these soils range from 1.4×10^{-4} cm/sec to 1.4×10^{-2} cm/sec.

b. North Bend ANGS

North Bend ANGS is located in Coos County, Oregon, in a lowland area consisting of forest, dunes and estuaries. The land is gently sloping and elevations generally do not exceed 20 feet. Adjacent to the Station is Siuslaw National Forest. The local soils consist of Templeton silt loam. The soil is well drained, and is formed in weathered colluvium. The surface layer is very dark brown to dark brown in color and is approximately 16 inches thick. The subsoil is reddish-brown to very brown silty clay loam, approximately 26 inches thick. Weathered sedimentary rock occurs at approximately 42 inches. Permeability rates for these soils range from 4.2×10^{-4} to 1.4×10^{-3} cm/sec.

C. Hydrology

1. Surface Water

a. Portland ANGB

Portland ANGB is within the boundaries of the 100-year floodplain. Surface waters from the Base eventually find their way into the Columbia River via small runs and branches, drainage ditches, and eventually small tributaries. To the south of the Base is the Columbia Slough, which is a drainage waterway that empties into the Columbia River.

b. North Bend ANGS

The surface water at North Bend ANGS consists of North Slough Creek to the south and Shutters Creek to the south. A Shutter Creek tributary flows north of the Station towards Tenmile Lake. North Slough Creek is the domestic water supply at the Station and housing complex. The creek yields 11,631 gallons/day.

2. Groundwater

Groundwater is obtained from the Columbia River Basalt, the Troutdale Formation, and from the unconsolidated Quaternary deposits. In Portland (Multnomah County), almost all supplies of water for individual and municipal facilities are drawn from the Bull Run River. The supply of water is a composite from the glacial runoffs and precipitation. A groundwater development program, Pilot Well Study, was conducted for the City of Portland Bureau of Water Works in 1978. Two of the three aquifers described in this study are of some concern, because of their proximity to the Portland ANGB. There is a potential risk for contamination of the Troutdale Sandstone Aquifer and Troutdale Gravel Aquifer because the depth to the aquifer can be as shallow as 20 feet, although its maximum depth is 335 feet.

At the Portland ANGB, groundwater flow is generally northwesterly towards the Columbia River, and the water table is shallow and variable. Groundwater levels are influenced by rainwater infiltration, runoff, and Columbia River water levels, but Columbia Slough water levels and pumpage from the Multnomah County Drainage District are the main controlling factors. Generally, the water table is lowest in the late summer and fall and highest in the winter and spring. Multnomah Drainage District pumping attempts to maintain slough water levels between 9.8 feet and 11.8 feet (from east to west) above mean sea level.

Groundwater at North Bend ANGS is shallow and can be found at depths less than six feet.

D. Critical Habitats/Endangered or Threatened Species

Documents sent by personnel from the Oregon Department of Fish and Wildlife disclosed that there are no endangered or threatened flora or fauna within one mile of Portland ANGB or North Bend ANGS.

There are no critical habitats, wetlands, or wilderness areas in the vicinity of Portland ANGB.

There are no critical habitats or wetlands in the vicinity of North Bend ANGS; however, the ANGS is adjacent to the Siuslaw National Forest and Elliott State Forest.

IV. SITE EVALUATION

A. Activity Review

A review of Base and Station records and interviews with past and present Base and Station employees at Portland ANGB and North Bend ANGS resulted in the identification of specific operations within each activity in which the majority of industrial chemicals are handled and hazardous wastes are generated. Tables 1 and 1A summarize the major operations associated with each activity, provides estimates of the quantities of waste currently being generated by these operations, and describes the past and present disposal practices. Any operation that is not listed in Tables 1 and 1A has been determined to produce negligible quantities of wastes requiring ultimate disposal. For example, small volumes of methyl ethyl ketone may be used on occasion, it commonly evaporates after use, and therefore it does not present a disposal problem. Conversely, if a particular volatile compound is listed, then the quantity represents an estimate of the amount actually disposed of according to the method shown.

B. Disposal/Spill Site Identification, Evaluation, and Hazard Assessment

Interviews with 19 Base personnel (Appendix A) and subsequent site inspections resulted in the identification of eight potentially contaminated disposal/spill sites on Portland ANGB and seven potentially contaminated disposal/spill sites on North Bend ANGS. Seven of the 15 sites present the potential for contamination migration (Step 4 of Figure 1), and six of these were further evaluated using HARM and assigned a HAS. Copies of the completed HARM scoring forms are found in Appendix C. Table 2 summarizes the HARM scores for each of the sites; brief descriptions of the sites follow. The locations of the potentially contaminated sites identified at Portland ANGB are illustrated in Figure 3, and the locations of the potentially contaminated sites identified at North Bend ANGS are illustrated in Figure 4.

Source: Portland ANGB, 1986

Potentially Contaminated Sites Identified at Portland ANGB, Portland, Oregon

Site No. 1 - Central Hazardous Waste Storage Area (HAS-44)

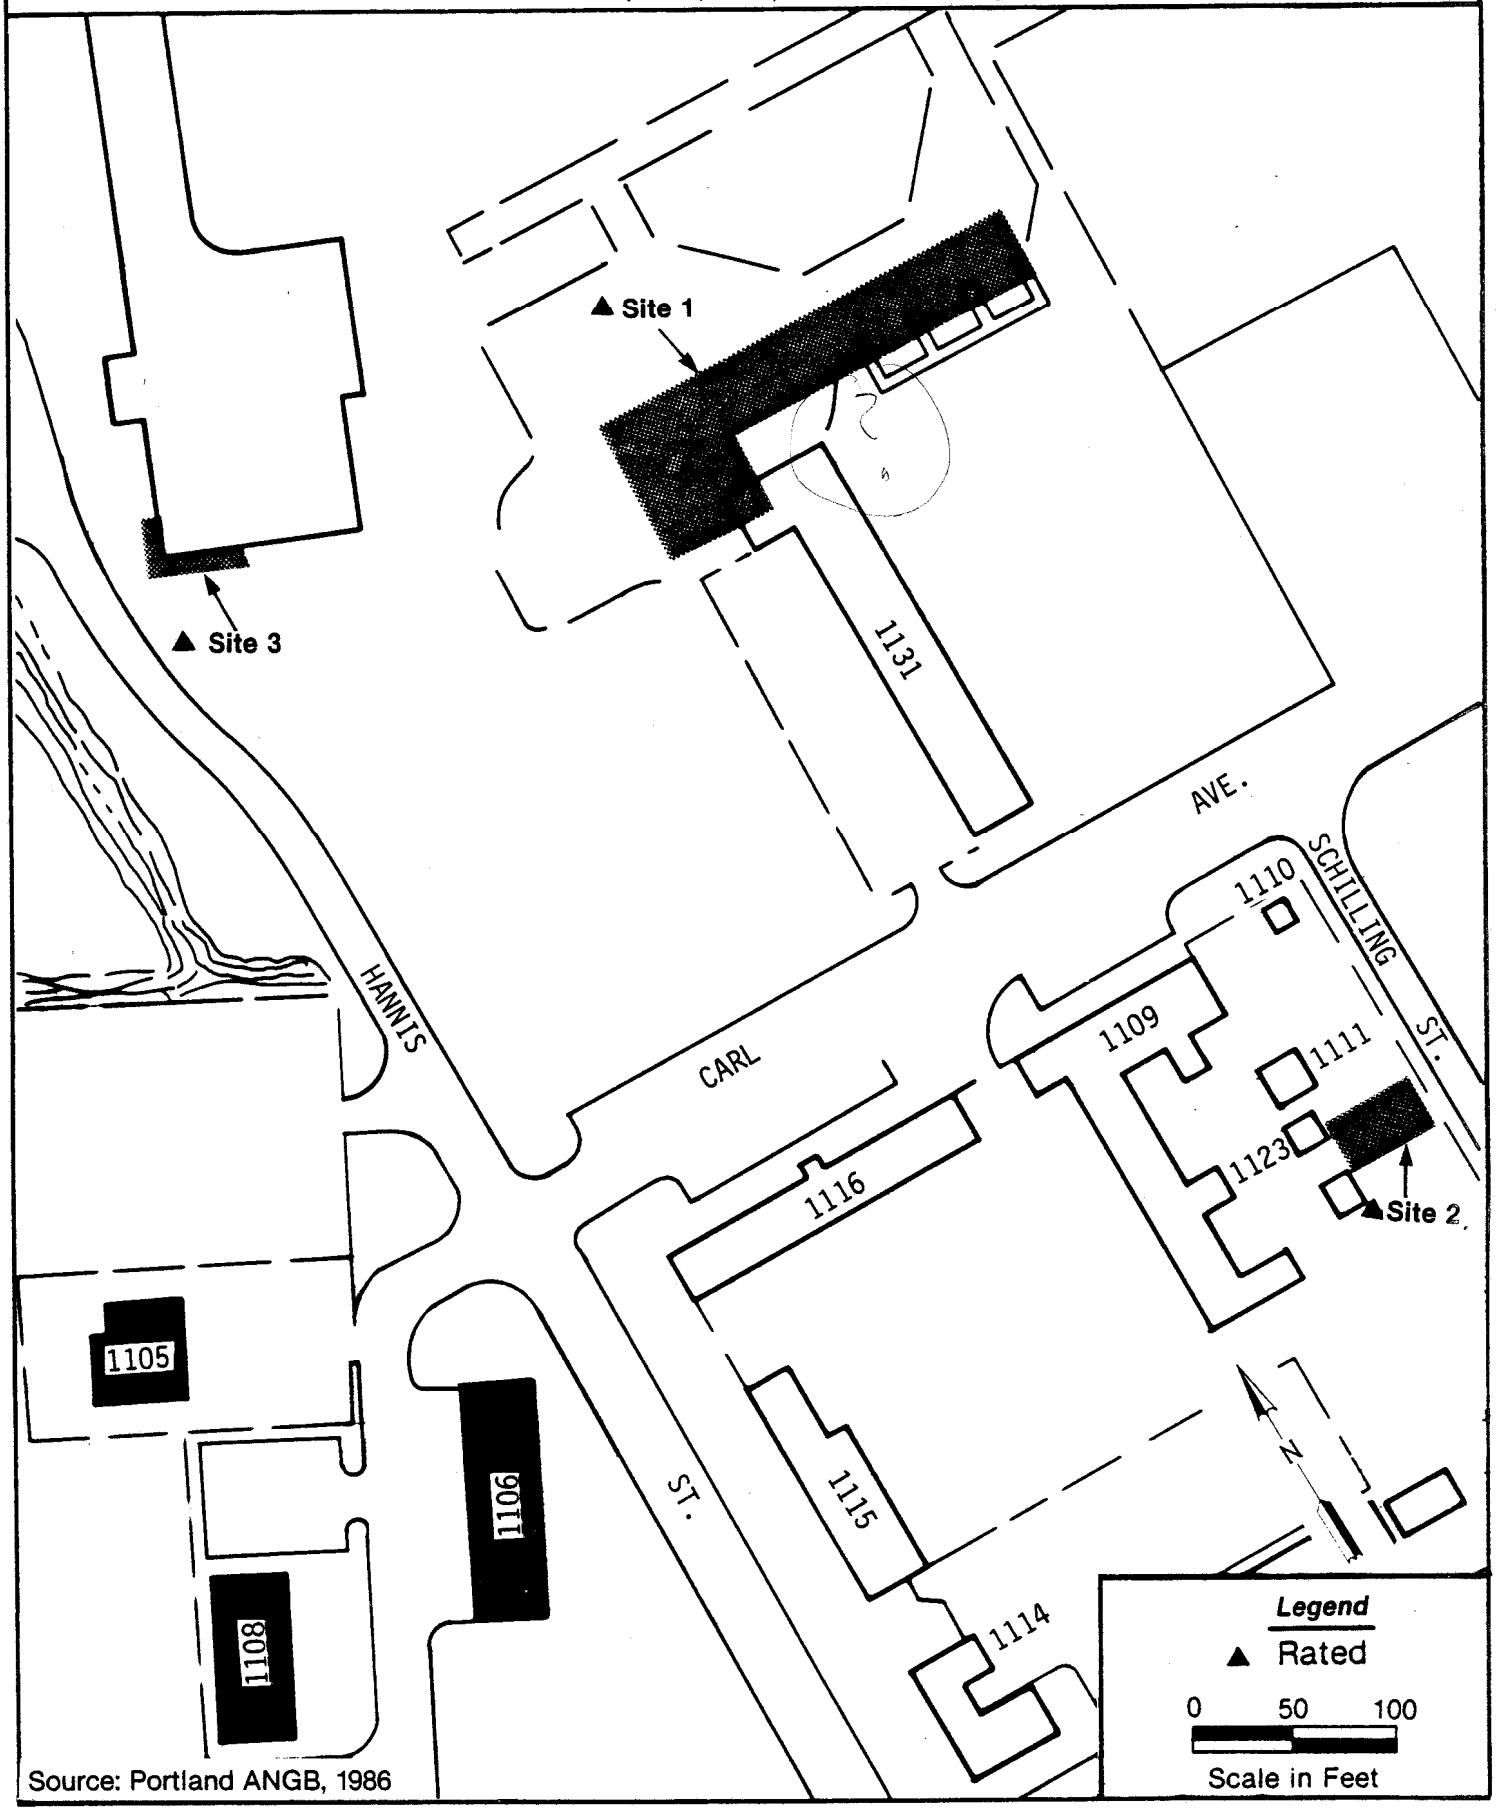
This hazardous waste temporary storage area is located adjacent to the northeast corner of Building 1131 (see Figure 3A). Since 1970, this site has been used for the temporary storage of 55-gallon drums containing waste oil, solvents, fuels, PD-680, DF-2, slop waste, and transformers and capacitors on pallets. The area consists of gravel with no containment structures. Discolored gravel and soil was observed throughout the area. No major spills have been recorded at this site, but because of the variety of the waste stored there and the presence of discolored gravel and soil, a HAS was necessary.

Site No. 2 - Civil Engineering Hazardous Material Storage Area (HAS-40)

The site is adjacent to Building 1123 on Schilling Street (see Figure 3A). The building is not enclosed and has an open gravel floor. Drums are stored in a horizontal position on steel legs. Other than drippings and seepage, no spills have been noted at this site. However, during the site inspection, the HMTC team observed the methyl ethyl ketone drum leaking from the faucet area, as well as discolored gravel throughout the storage area. For these reasons, a HAS was deemed necessary.

Site No. 3 - Hush House Area (HAS-44)

HMTC observed discolored soil and grass throughout the Hush House Area (see Figure 3A). The oil/water separator and/or the holding tank could be a contributing factor. Interviewees had indicated that the oil/water separator was not functioning properly and there are no records of when the holding tank was last pumped out. Due to the evidence of past leakage, a HAS was necessary.



Site No. 4 - Main Drainage Ditch (HAS-50)

The Portland ANGB personnel indicated that numerous fuel spills have occurred at this site over the past five years (see Figure 3B). JP-4, AVGAS, diesel

HMTC

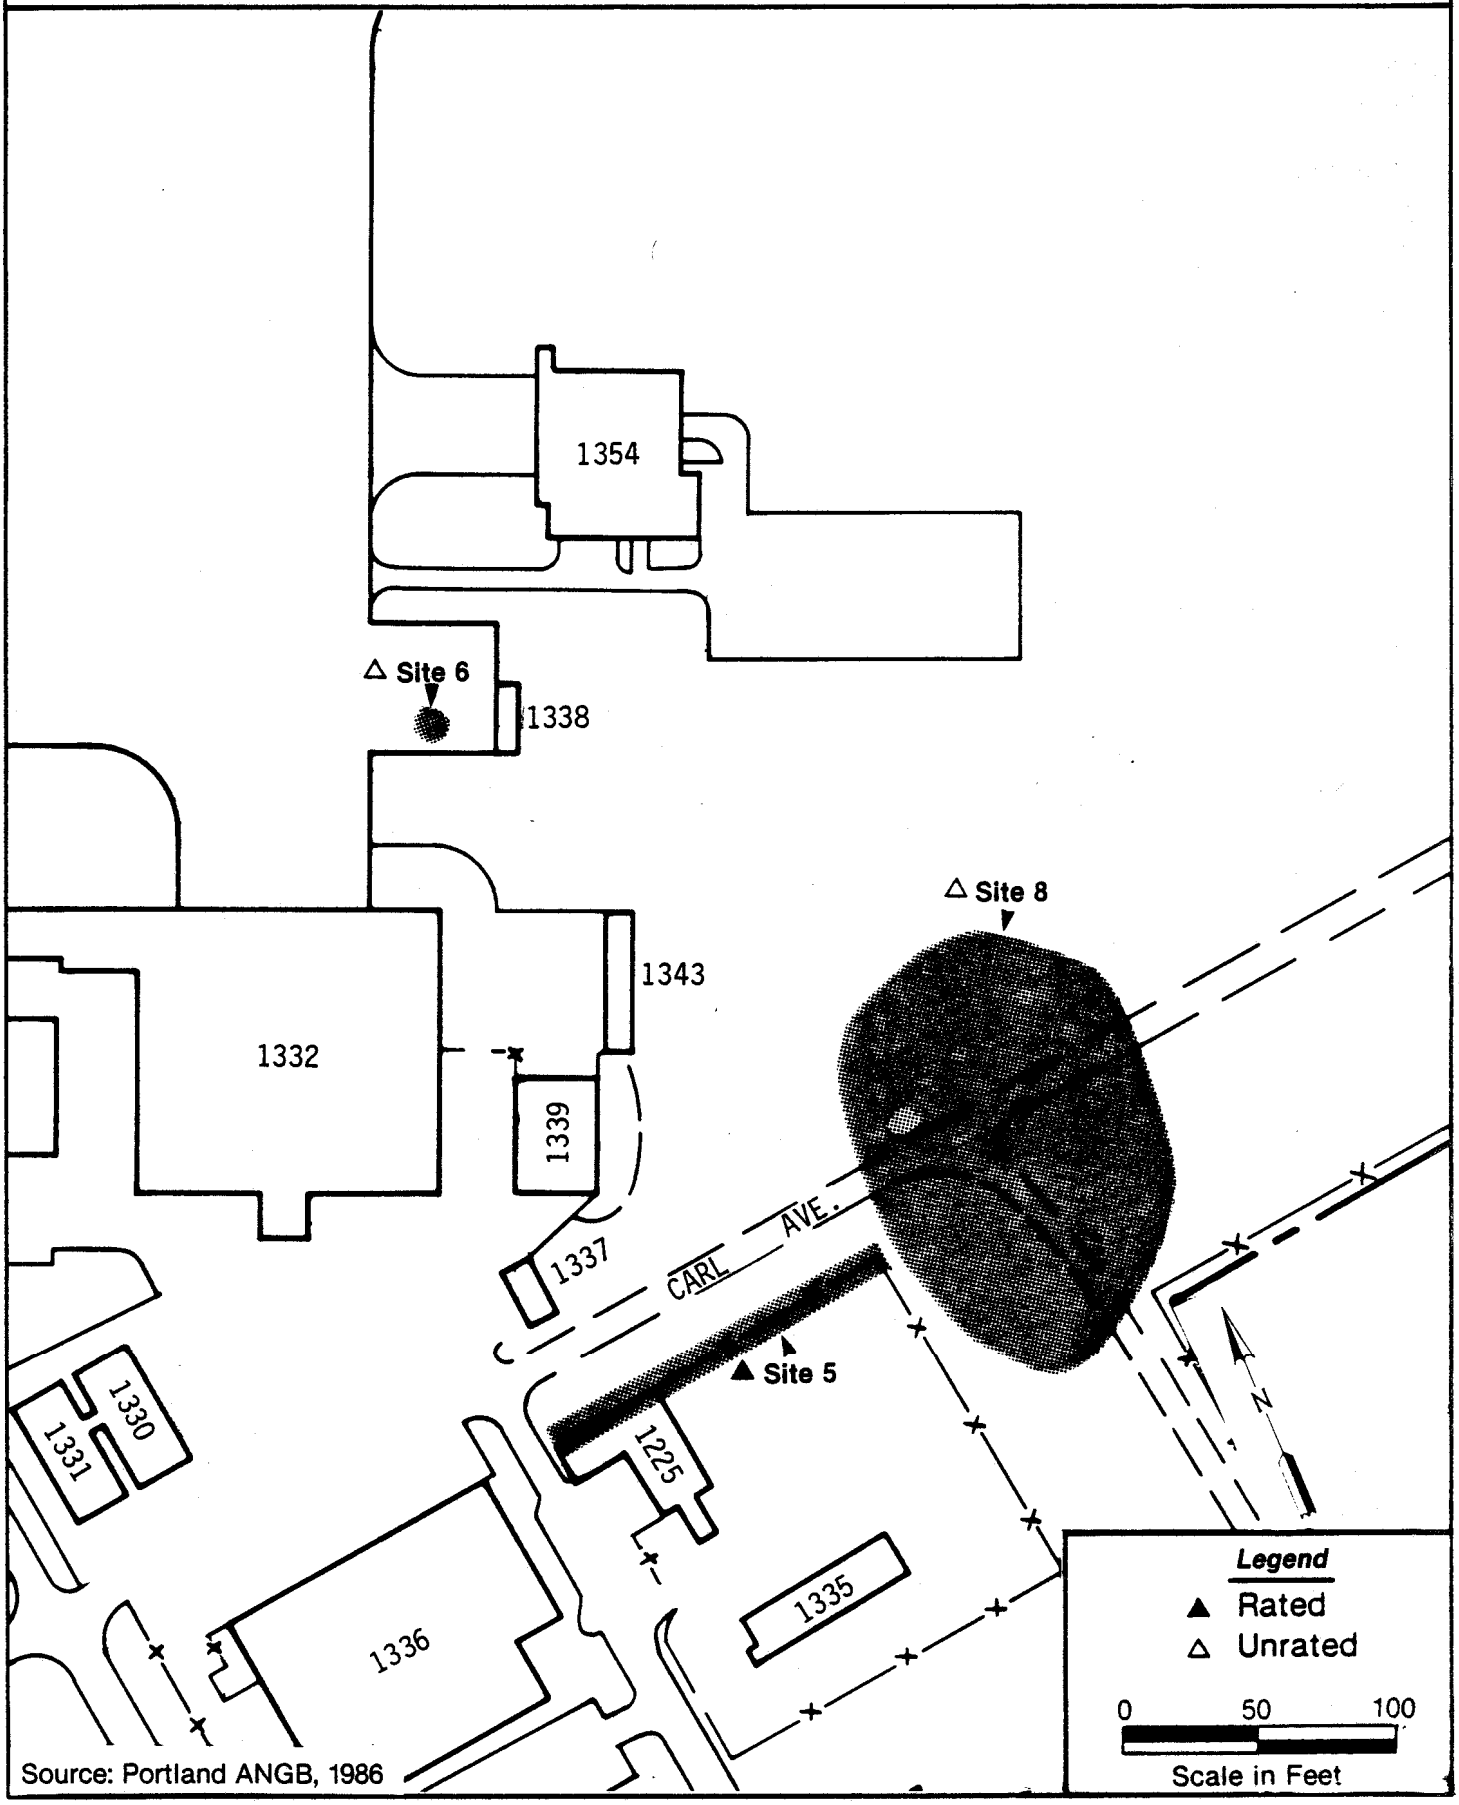
and any other HW/HM from runways, aprons, and other paved areas which are not readily absorbed into the ground, ultimately find their way into the Base drainage ditch system either directly, through storm drain openings, or via rainwater runoff.

The aircraft apron areas, where fuel and oil spills occur, are drained by pipes and ditches and are not connected to pollution control facilities. Some of the inlets in these areas have submerged outlets which provide some retention of floatables, but for large spills or during heavy rainfall such devices are inadequate to prevent fuel or oil from escaping. According to interviewees, fuel and oil have often been evident in the drainage ditches downstream from the apron area.

Running water flows through the Base drainage system only during periods of precipitation. Consequently, small spills and industrial discharges do not always flow directly offbase, but would more likely tend to accumulate in areas proximate to actual points of discharge. For this reason, areas along the apron and runway drainage ditch system are most suspect.

Thus, through a combination of spills, industrial discharges, or dumping, it is probable that the Base drainage ditch system has received a substantial quantity of contaminants over the years. For this reason, the Base drainage ditch system is considered as a potential hazardous waste site with high contaminant migration potential, and a HAS is deemed necessary.



Site No. 5 - AGE Maintenance Shop (HAS-40)

This site is adjacent to Building 1225 on Carl Street (see Figure 3C). The Base motor pool used this area until 1972. Along the fence on the northeast side of Building 1225, the HMTC survey team observed discolored soil, gravel, and stressed vegetation. The area along the fence was used to drain batteries, and buckets of oil and solvent were also occasionally dumped in this area. Thus, this site received a HAS.

HMTC

Figure 3C.

Location of Site Nos. 5, 6 and 8 at Portland International Airport (ANG) Portland, Oregon.

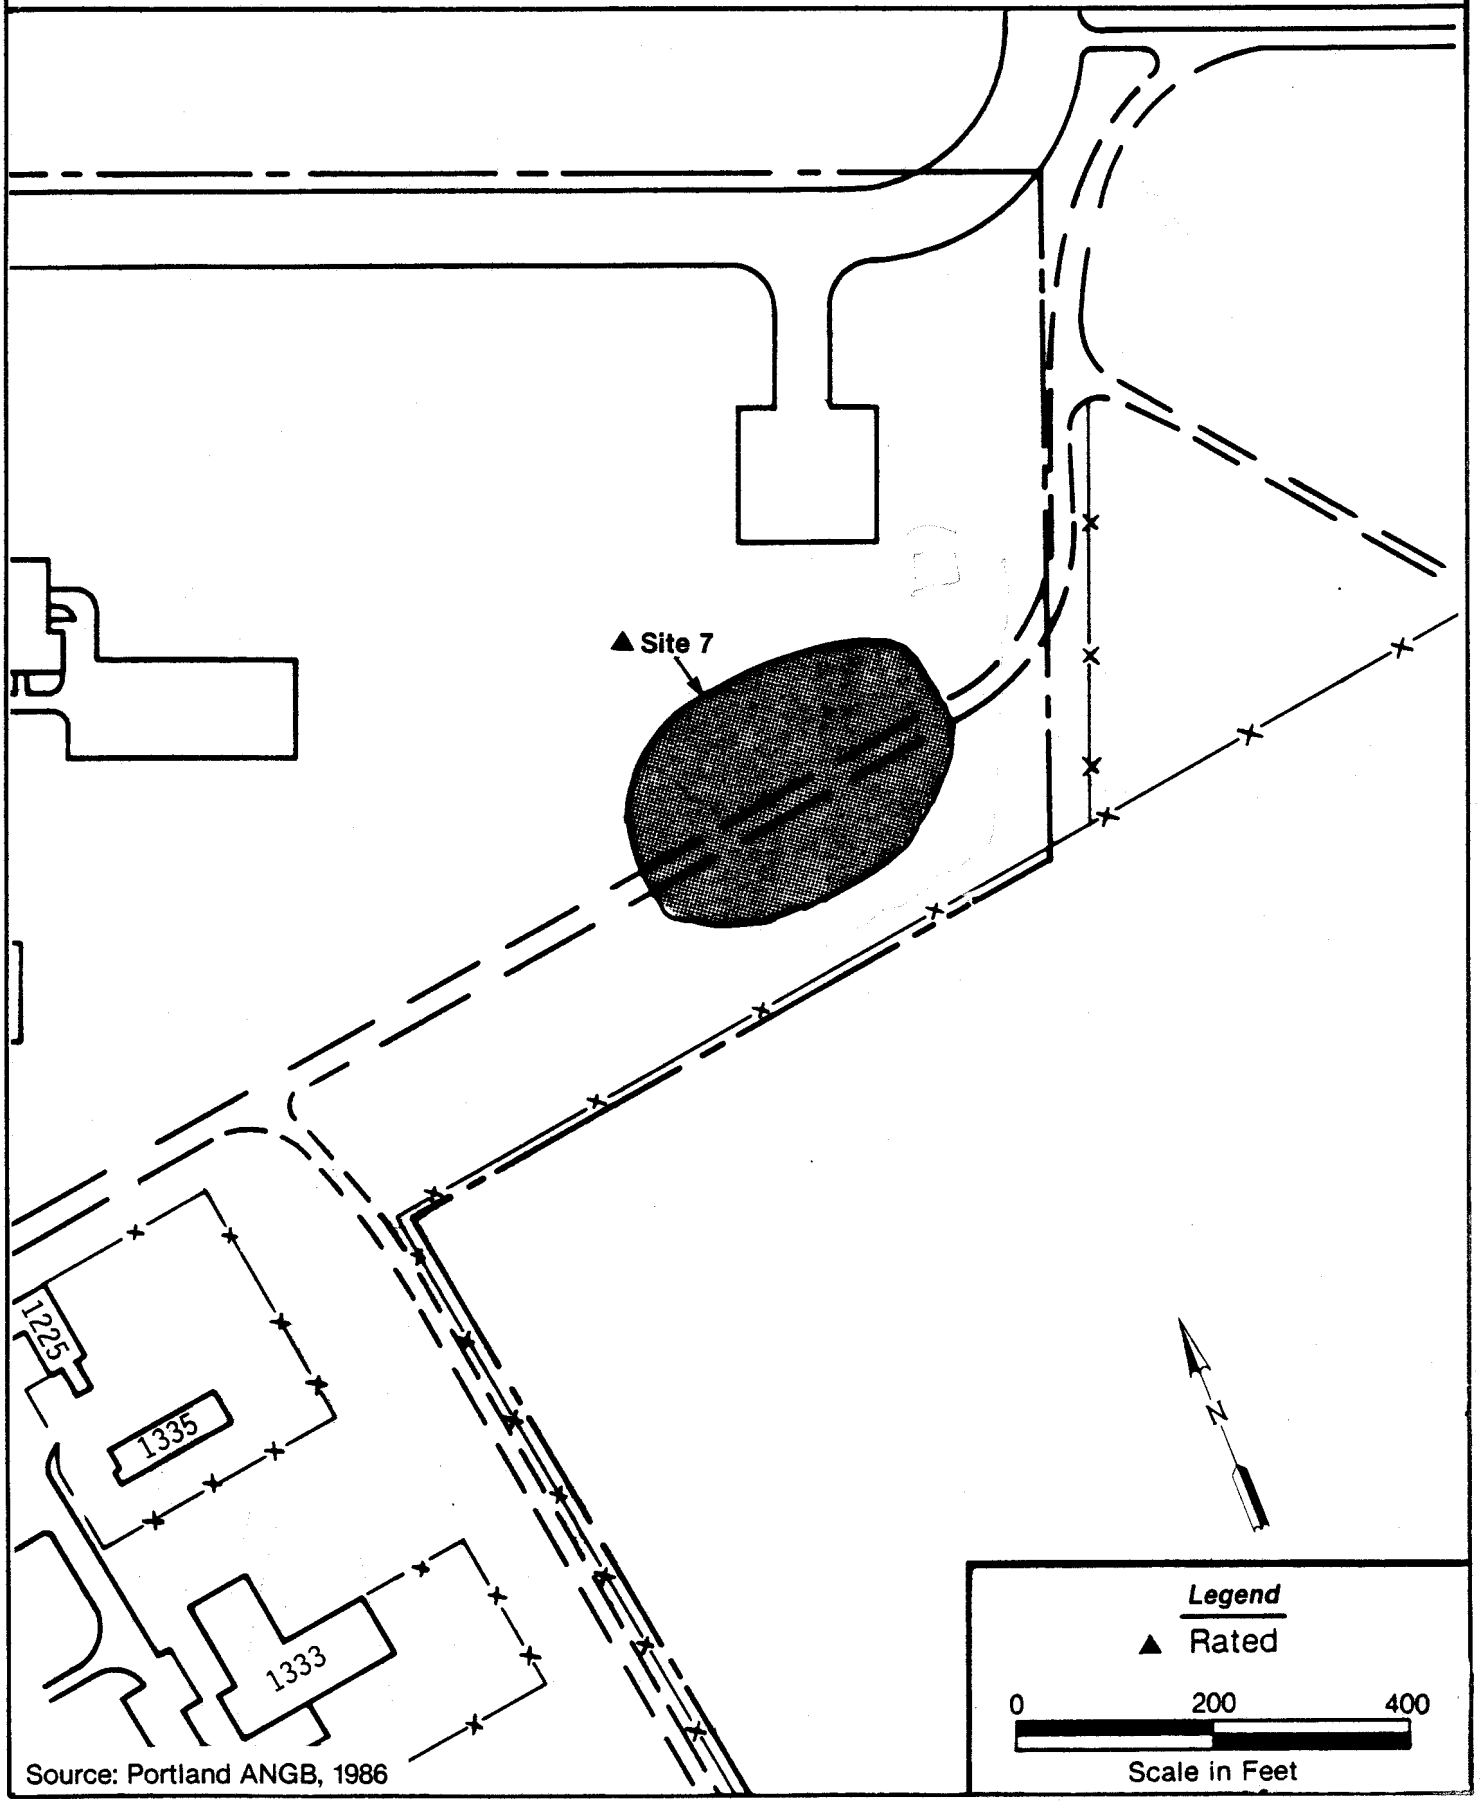
Source: Portland ANGB, 1986

Site No. 6 - Wash Rack West of Building 1355 (Unscored)

The oil/water separator is used to collect residual oil and soapy water from the wash down area (see Figure 3C). Interviews noted that the oil/water separator was hooked up to the sanitary sewer lines in 1984; however, there were no records to indicate the removal of waste oil. There were no signs of contamination or environmental stress in this area, and no reason to believe any HM/HW entered the system, so no HAS was necessary.

Site No. 7 - Burn Pit Area (HAS-50)

The burn pit area is located on the northeast side of the Base off Carl Avenue, and operated from 1957 to 1978 (see Figure 3D). The open pit area served as a fire training area. JP-4 and various flammable substances possibly contained some waste shop solvents, which were ignited in the burn pit. There are no visible containment structures or berms at the burn pit area. It is estimated that several thousand gallons of flammable liquids may have been disposed of in the pit each year; therefore, a HAS was necessary.



Site No. 8 - Sanitary Landfill (Unscored)

This site is located north of east Perimeter Road and Carl Avenue (see Figure 3C). The landfill was operated by the Air Force from 1950 to 1964, and was used by the ANGB until the mid 1970's. After reviewing all information presented during the Records Search, it was determined that there is no direct evidence of any HW/HM having been disposed of at this landfill. There were no areas of accumulated drums or containers which would appear to have contained HW/HM, and there were no indications of chemical odors. Based on information provided, the site could not be assigned a HAS. However, experience with similar types of Air National Guard sanitary landfills indicates the need for limited investigation at this site. If the recommended investigation indicates pollutant levels above standard acceptable levels, further action, including a HAS and further investigative activities, should be performed.

HMTC

Figure 3D.

Location of Site No. 7 Sites at Portland International Airport (ANG) Portland, Oregon

Source: Portland ANGB, 1986

Potentially Contaminated Sites Identified at North Bend ANGS, North Bend, Oregon

Site No. 9 - Transformer Area (Unscored)

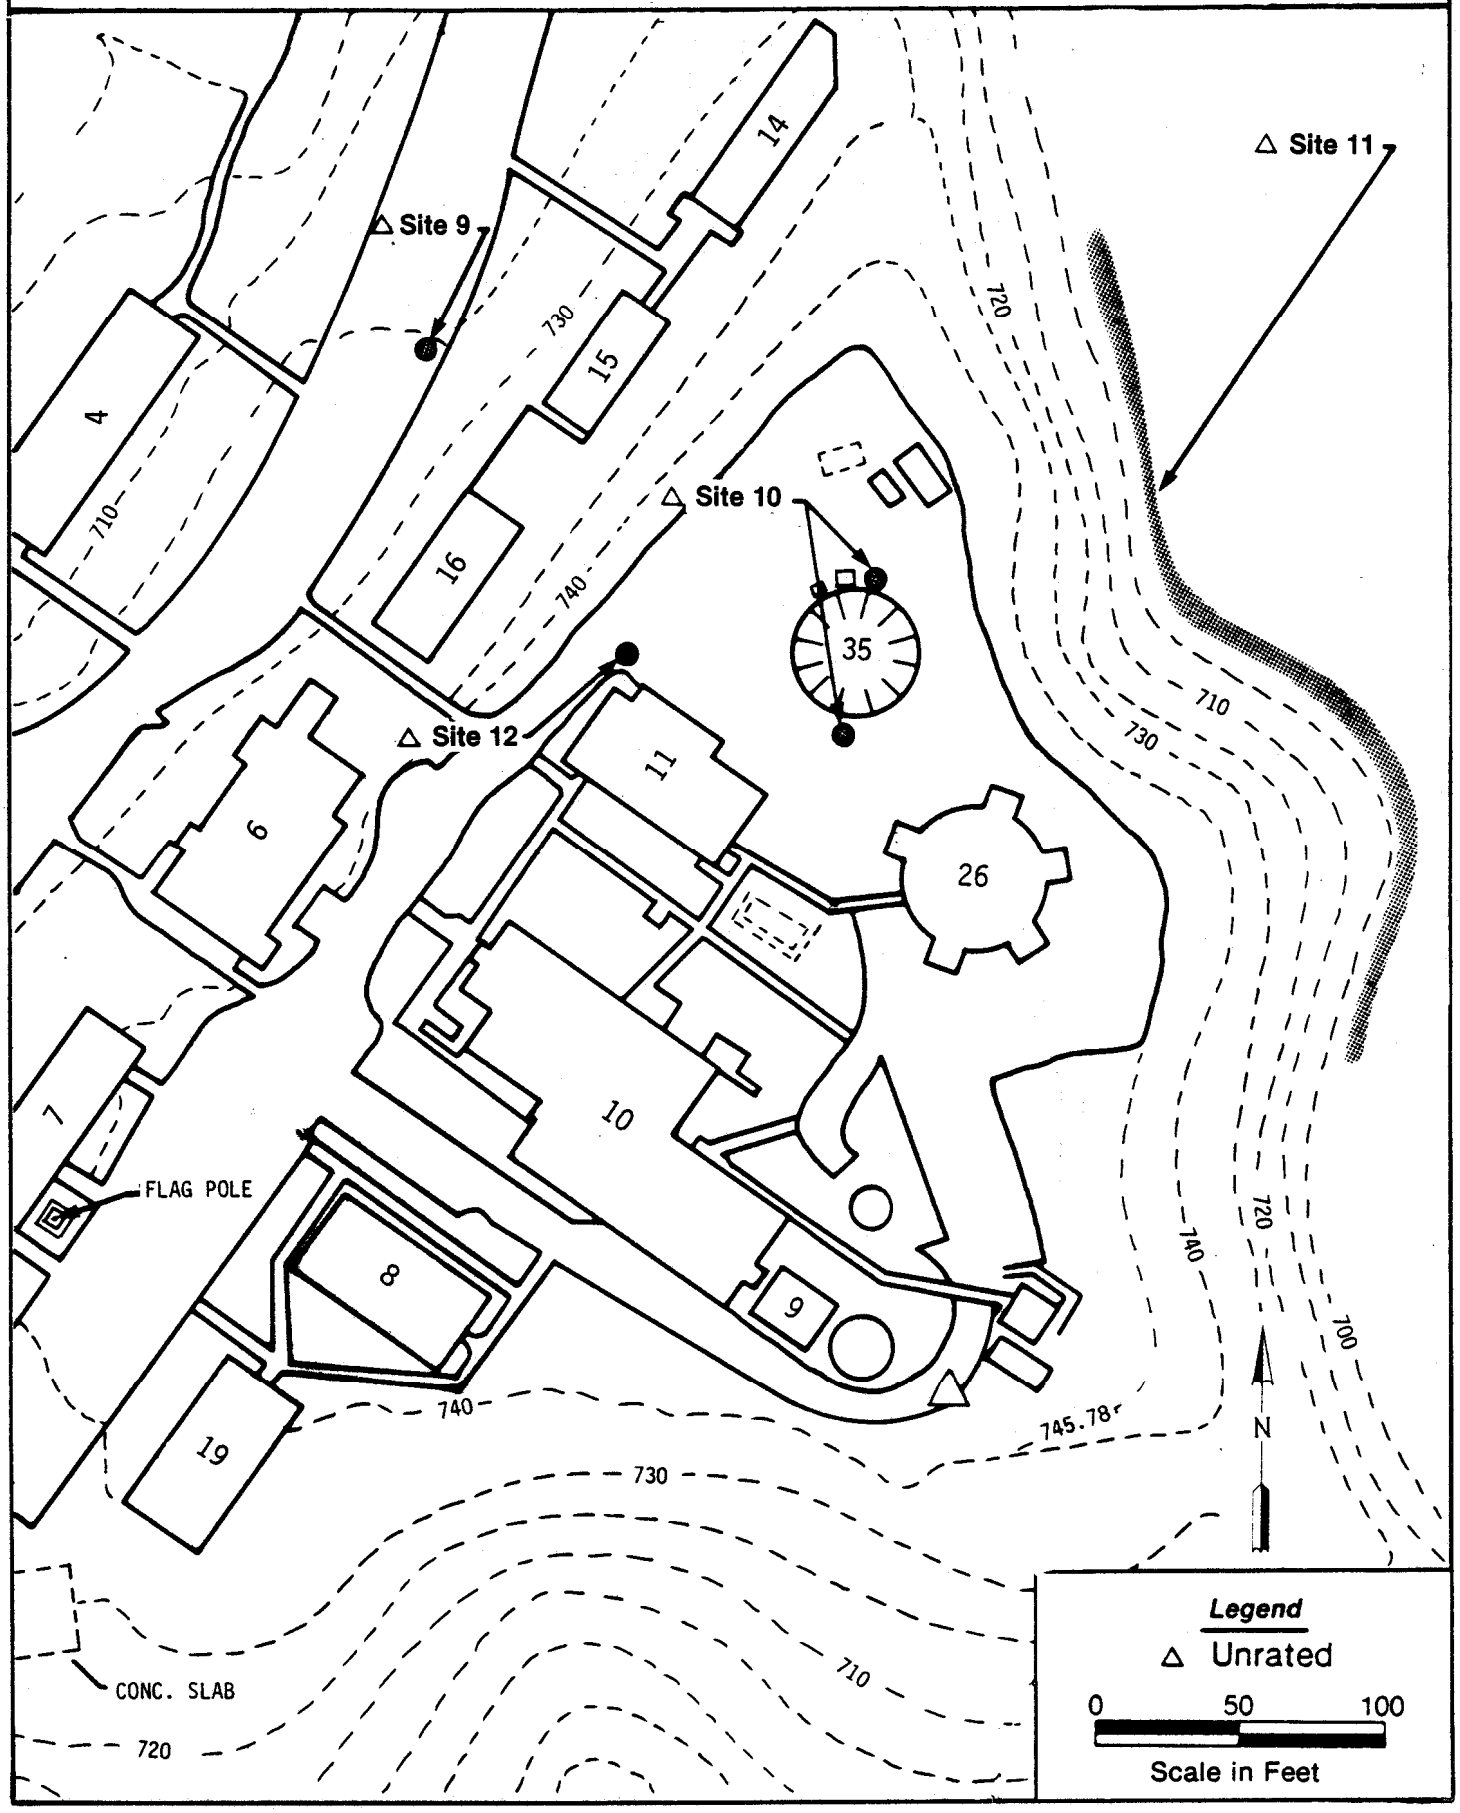
In 1984 and 1985, there was evidence of several transformers leaking from a utility pole (see Figure 4A). Samples were taken from the transformer and the soil. Analytical results reported values less than the detection limit of 5 mg/kg for PCBs. See Appendix D for oil sample analytical results. Since the site poses no threat to health or the environment, further evaluation and a HAS are not necessary.

Site No. 10 - Chemical Disposal Area (Unscored)

This area is adjacent to Building 35 (see Figure 4A). From 1965 to 1979, the area was occasionally used to dispose of small quantities (approximately one cup) of tetrachloroethylene, methyl ethyl ketone, waste oil, and ethylene glycol. The area shows no signs of vegetative stress. A HAS was not necessary due to the small amounts of chemicals involved.

Site No. 11 - Mechanical and Electrical Components (Unscored)

This area is located on the southeast side of the ANGS (see Figure 4A). Unknown quantities of electrical and mechanical components were discarded by disposing of them over the hillside. Review of all available information indicated that there is no direct evidence of HM/HW having been disposed of at this site. As such, a HAS was not necessary.



Site No. 12 - Underground Storage Tank (Unscored)

An underground, 10,000 gallon storage tank is located North of Building 11 (see Figure 4A). The tank is presently used to store waste oils. There were no signs of past or present leakage or spillage, and no HAS is required.

HMTC

Figure 4A.

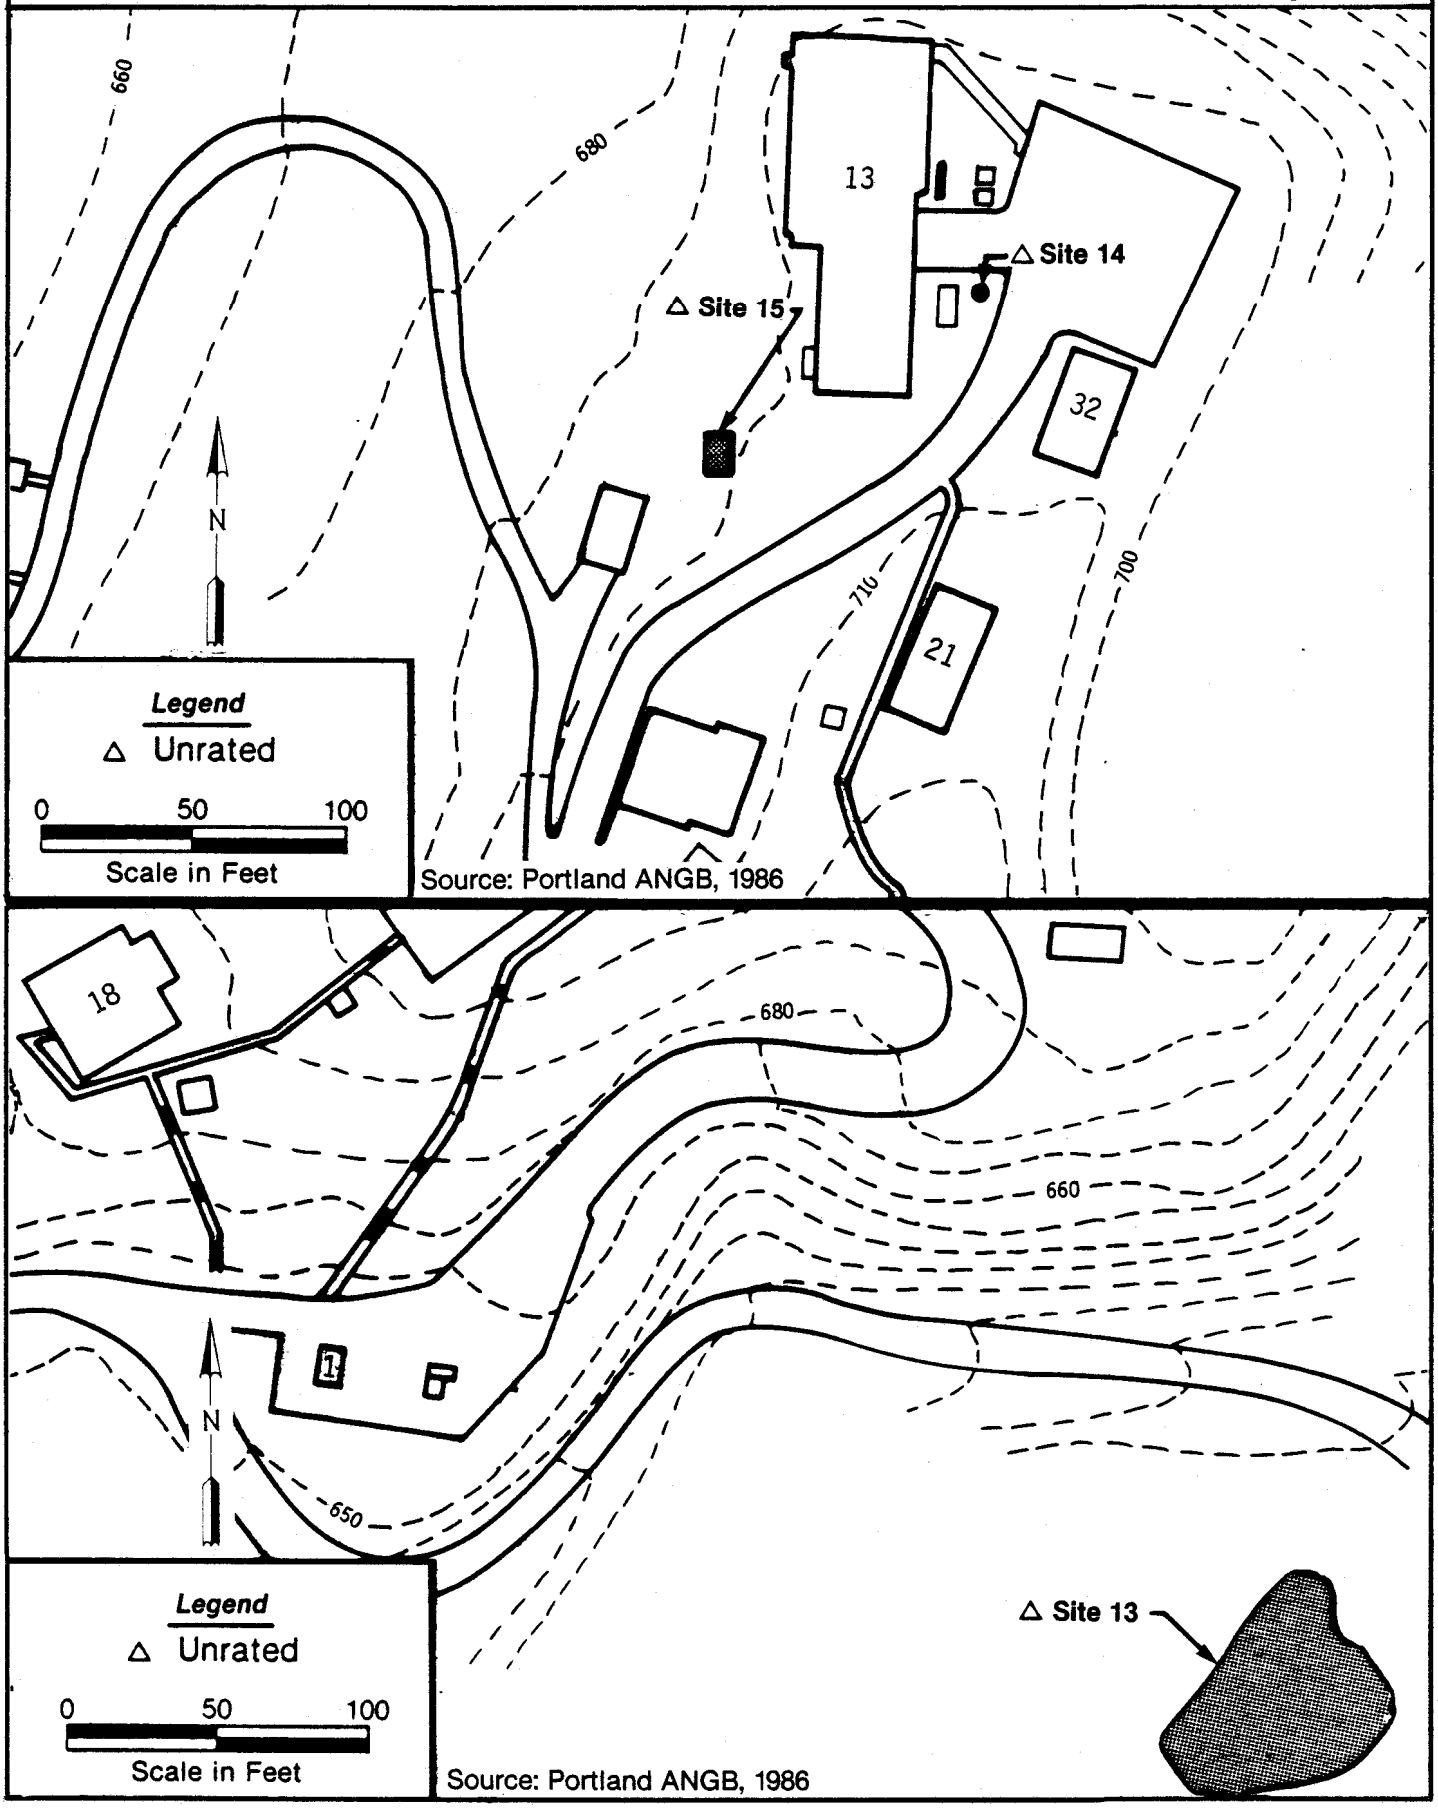
Location of Site Nos. 9, 10, 11 and 12, at North Bend Air National Guard Station, North Bend, Oregon.

Site No. 13 - Construction Debris (Unscored)

This area is located on the south end of the ANGS (see Figure 4B). Interviewees reported that unknown amounts of construction debris were disposed of at this site, including carpentry, welding, plastic, and asbestos materials. The presence of asbestos could not be confirmed, nor was there any evidence to confirm the presence of any hazardous wastes. As such, a HAS and further evaluation are not required.

Site No. 14 - DF-2 Spill (Unscored)

Interviewees reported a 1984 No. 2 Diesel fuel spill of approximately 100 gallons (see Figure 4B). No data exists on whether any of the fuel was recovered. An inspection of the site failed to turn up any evidence of the spill and no environmental stress was present. As such, it was determined that a HAS was not necessary.



Site No. 15 - Oil Drum Storage Area (Unscored)

The oil drum storage area, adjacent to Building 34 (see Figure 4B) is a totally enclosed wooden shed, approximately 8-1/2 x 11 feet in size. The building is used for storing ground maintenance equipment and small amounts of oil, gasoline, and solvents. During the Records Search, interviewees disclosed that past tenants used the building for storing oils, solvents, gasoline and, at one time, electrical transformers. The HMTC survey team observed oily discolored soil and vegetative stress over a 3 ft^2 area. However, because the ANGS is in a dense forest and no residential development exists within a 1-mile radius, this site causes no significant environmental impact. A HAS was deemed unnecessary.

HMTC

Figure 4B.

Locations of Site Nos. 13, 14 and 15, at North Bend Air National Guard Station, North Bend, Oregon

C. Other Pertinent Findings

- Sanitary sewage is treated municipally, offbase for Portland ANGB and North Bend ANGS.
- There are no active landfills on either property.
- Waste oils have never been used for road dust control on either property.
- No environmental monitoring has been conducted onbase, to date, at Portland ANGB.
- Radioactive waste has never been disposed of on either Base property.
- There are no current operating FTAs at either Base.
- Hazardous wastes are removed by private contractor from each Base on an as-needed basis.
- There are no ordinance disposal sites on either property.
- There are only small amounts of pesticides stored on either Base property.
- Significant pollution apparently enters the Portland ANGB drainage ditch near Building 729 through a pipe coming from an area to the north of the Base. This ditch is downstream of the new western boundary of the Base and will not concern the Air National Guard after the property is transferred to the Port Authority.

V. CONCLUSIONS

- Information obtained through interviews with 19 Base and Station personnel, review of Base and Station records, and field observations have resulted in the identification of eight potentially contaminated disposal and/or spill sites at the Portland ANGB, Portland, and seven sites at North Bend ANGS.

- No evidence of offbase environmental stress resulting from spills or disposal of HW/HM was observed in the immediate vicinity of Portland ANGB or North Bend ANGS.

- Six of the nineteen potential sites (Site Nos. 1, 2, 3, 4, 5, and 7) have been scored using the Air Force HARM.

- Nine sites (Site Nos. 6, 8, 9, 10, 11, 12, 13, 14, and 15) were eliminated from further study because it was concluded that they exhibit no potential for contaminant migration and therefore pose no significant hazards to health and welfare. Site Nos. 15 elimination is contingent upon sampling results.

VI. RECOMMENDATIONS

There is potential for contaminant migration at Portland ANGB; therefore, initial stages of the IRP Phase II/IVA are recommended. The purpose of further IRP work is to confirm or refute the presence of contamination at the sites. If confirmation is made, subsequent investigative efforts should be accomplished in order to fully characterize the extent of any soil and groundwater contamination. Requirements for those efforts would be outlined in the Phase II/IVA Statement of Work (SOW), if they are needed.

Site No. 1 - Central Hazardous Waste Storage Area

Further IRP analysis is required at this site to determine if contamination exists.

Site No. 2 - Civil Engineering Hazardous Material Storage Area

Further IRP analysis is required at this site to determine if contamination exists.

Site No. 3 - Hush House Area

Further IRP analysis is required at this site to determine if contamination exists.

Site No. 4 - Main Drainage Ditch

Further IRP analysis is required at this site to determine if contamination exists.

Site No. 5 - AGE Maintenance Shop

Further IRP analysis is required at this site to determine if contamination exists.

Site No. 7 Burn Pit Area

Further IRP analysis is required at this site to determine if contamination exists.

Site No. 8 - Sanitary Landfill

Further IRP analysis is required at this site to determine if contamination exists.

GLOSSARY OF TERMS

AQUICLUDE - A confining bed that prevents the flow of water to or from an adjacent aquifer.

AQUIFER - A geologic formation, or group of formations, that contains sufficient saturated permeable material to conduct groundwater and to yield economically significant quantities of groundwater to wells and springs.

AQUITARD - A confining bed that retards but does not prevent the flow of water to or from an adjacent aquifer.

CONE OF DEPRESSION - A depression of the water table or potentiometric surface surrounding a discharge well which is more or less the shape of an inverted cone.

CONTAMINANT - As defined by Section 101(f)(33) of Superfund Amendments and Reauthorization Act of 1986 (SARA) shall include, but not be limited to, any element, substance, compound, or mixture, including disease-causing agents, which after release into the environment and upon exposure, ingestion, inhalation, or assimilation into any organism, either directly from the environment or indirectly by ingestion through food chains, will or may reasonably be anticipated to cause death, disease, behavioral abnormalities, cancer, genetic mutation, physiological malfunctions (including malfunctions in reproduction), or physical deformation in such organisms or their offspring; except that the term "contaminant" shall not include petroleum, including crude oil or any fraction thereof which is not otherwise specifically listed or designated as a hazardous substance under

(a) any substance designated pursuant to Section 311(b)(2)(A) of the Federal Water Pollution Control Act,

(b) any element, compound, mixture, solution, or substance designated pursuant to Section 102 of this Act,

(c) any hazardous waste having the characteristics identified under or listed pursuant to Section 3001 of the Solid Waste Disposal Act (but not including any waste the regulation of which under the Solid Waste Disposal Act has been suspended by Act of Congress),

(d) any toxic pollutant listed under Section 307(a) of the Federal Water Pollution Control Act,

(e) any hazardous air pollutant listed under Section 112 of the Clean Air Act, and

(f) any imminently hazardous chemical substance or mixture with respect to which the administrator has taken action pursuant to Section 7 of the Toxic Substance Control Act;

and shall not include natural gas, liquefied natural gas, or synthetic gas of pipeline quality (or mixtures of natural gas and such synthetic gas).

CRITICAL HABITAT - The native environment of an animal or plant which, due either to the uniqueness of the organism or the sensitivity of the environment, is susceptible to adverse reactions in response to environmental changes such as may be induced by chemical contaminants.

DISCHARGE - The release of any waste stream or any constituent thereof to the environment which is not recovered.

DOWNGRADIENT - A direction that is topographically or hydraulically downslope; the direction in which groundwater flows.

ENDANGERED SPECIES - Wildlife species that are designated as endangered by the U.S. Fish and Wildlife Service.

GROUNDWATER - Refers to the subsurface water that occurs beneath the water table in soils and geologic formations that are fully saturated.

HARM - Hazard Assessment Rating Methodology - A system adopted and used by the United States Air Force to develop and maintain a priority listing of potentially contaminated sites on installations and facilities for remedial action based on potential hazard to public health, welfare, and environmental impacts. (Reference: DEQPPM 81-5, 11 December 1981).

HAS - Hazard Assessment Score - The score developed by utilizing the Hazardous Assessment Rating Methodology (HARM).

HAZARDOUS MATERIAL - Any substance or mixture of substances having properties capable of producing adverse effects on the health and safety of the human being. Specific regulatory definitions also found in OSHA and DOT rules.

HAZARDOUS WASTE - A solid or liquid waste that, because of its quantity, concentration, or physical, chemical, or infectious characteristics may

a. cause, or significantly contribute to, an increase in mortality or an increase in serious irreversible or incapacitating reversible illness or

b. pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, disposed of, or otherwise managed.

HYDRAULIC CONDUCTIVITY - The rate at which water can move through a permeable medium.

HYDRAULIC GRADIENT - The difference in head (elevation of water surface) at two points divided by the distance between these two points.

MIGRATION (Contaminant) - The movement of contaminants through pathways (groundwater, surface water, soil, and air).

PERMEABILITY - The capacity of a porous rock, sediment, or soil for transmitting a fluid without impairment of the structure of the medium; it is a measure of the relative ease of fluid flow under unequal pressure.

STRATA - Distinguishable horizontal rock layers separated vertically from other layers.

SURFACE WATER - All water exposed at the ground surface, including streams, rivers, ponds, and lakes.

THREATENED SPECIES - Wildlife species that are designated as threatened by the U.S. Fish and Wildlife Service.

UPGRADIENT - A direction that is topographically or hydraulically upslope.

WATER TABLE - The upper limit of the portion of the ground that is wholly saturated with water.

WETLANDS - Those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas.

WILDERNESS AREA - An area unaffected by anthropogenic activities and deemed worthy of special attention to maintain its natural condition.

USAF Hazard Assessment Rating Methodology

USAF HAZARD ASSESSMENT RATING METHODOLOGY

The Department of Defense (DoD) has established a comprehensive program to identify, evaluate, and control problems associated with past disposal practices at DoD facilities. One of the actions required under this program is to:

> develop and maintain a priority listing of contaminated installations and facilities for remedial action based on potential hazard to public health, welfare, and environmental impacts. (Reference: DEQPPM 81-5, 11 December 1981).

Accordingly, the United States Air Force (USAF) has sought to establish a system to set priorities for taking further actions at sites based upon information gathered during the Records Search phase of its Installation Restoration Program (IRP).

PURPOSE

The purpose of the site rating model is to provide a relative ranking of sites of suspected contamination from hazardous substances. This model will assist the Air National Guard in setting priorities for follow-on site investigations.

This rating system is used only after it has been determined that (1) potential for contamination exists (hazardous wastes present in sufficient quantity), and (2) potential for migration exists. A site can be deleted from consideration for rating on either basis.

DESCRIPTION OF MODEL

Like the other hazardous waste site ranking models, the U.S. Air Force's site rating model uses a scoring system to rank sites for priority attention. However, in developing this model, the designers incorporated some special features to meet specific DoD program needs.

The model uses data readily obtained during the Records Search portion (Phase I) of the IRP. Scoring judgment and computations are easily made. In assessing the hazards at a given site, the model develops a score based on the most likely routes of contamination and the worst hazards at the site. Sites are given low scores only if there are clearly no hazards. This approach meshes well with the policy for evaluating and setting restrictions on excess DoD properties.

Site scores are developed using the appropriate ranking factors according to the method presented in the flow chart (Figure 1 of this report). The site rating form and the rating factor guideline are provided at the end of this appendix.

As with the previous model, this model considers four aspects of the hazard posed by a specific site: possible receptors of the contamination, the waste and its characteristics, the potential pathways for contamination migration, and any efforts that were made to contain the wastes resulting from a spill.

The receptors category rating is based on four rating factors: the potential for human exposure to the site, the potential for human ingestion of contaminants should underlying aquifers be polluted, the current and anticipated uses of the surrounding area, and the potential for adverse effects upon important biological resources and fragile natural settings. The potential for human exposure is evaluated on the basis of the total population within 1,000 feet of the site, and the distance between the site and the base boundary. The potential for human ingestion of contaminants is based on the distance between the site and the nearest well, the groundwater use of the uppermost aquifer, and population served by the groundwater supply within 3 miles of the site. The uses of the surrounding area are determined by the zoning within a 1-mile radius. Determination of whether or not critical environments exist within a 1-mile radius of the site predicts the potential for

adverse effects from the site upon important biological resources and fragile natural settings. Each rating factor is numerically evaluated (0-3) and increased by a multiplier. The maximum possible score is also computed. The factor score and maximum possible scores are totaled, and the receptors subscore computed as follows: receptors subscore = (100 x factor score subtotal/ maximum score subtotal).

The waste characteristics category is scored in three steps. First, a point rating is assigned based on an assessment of the waste quantity and the hazard (worst case) associated with the site. The level of confidence in the information is also factored into the assessment. Next, the score is multiplied by a waste persistence factor, which acts to reduce the score if the waste is not very persistent. Finally, the score is further modified by the physical state of the waste. Liquid wastes receive the maximum score, while scores for sludges and solids are reduced.

The pathways category rating is based on evidence of contaminant migration or an evaluation of the highest potential (worst case) for contaminant migration along one of three pathways: surface-water migration, flooding, and groundwater migration. If evidence of contaminant migration exists, the category is given a subscore of 80 to 100 points. For indirect evidence, 80 points are assigned, and for direct evidence, 100 points are assigned. If no evidence is found, the highest score among the three possible routes is used. The three pathways are evaluated and the highest score among all four of the potential scores is used.

The scores for each of the three categories are added together and normalized to a maximum possible score of 100. Then the waste management practice category is scored. Scores for sites with no containment are not reduced. Scores for sites with limited containment can be reduced by 5 percent. If a site is contained and well managed, its score can be reduced by 90 percent. The final site score is calculated by applying the waste management practices category factory to the sum of the scores for the other three categories.

1. RECEPTORS CATEGORY

Rating Factors	Rating Scale Levels 0	1	2	3	Multiplier
A. Population within 1,000 feet (includes on-base facilities)	0	1-25	26-100	Greater than 100	4
B. Distance to nearest water well	Greater than 3 miles	1 to 3 miles	3,001 feet to 1 mile	0 to 3,000 feet	10
C. Land Use/Zoning (within 1-mile radius)	Completely remote (zoning not applicable)	Agricultural	Commercial or Industrial	Residential	3
D. Distance to installation boundary	Greater than 2 miles	1 to 2 miles	1,001 feet to 1 mile	0 to 1,000 feet	6
E. Critical environments (within 1-mile radius)	Not a critical environment	Natural areas	Pristine natural areas; minor wetlands; preserved areas; presence of economically important natural resources susceptible to contamination	Major habitat of an endangered or threatened species; presence of recharge area; major wetlands	10
F. Water quality/use designation of nearest surface water body	Agricultural or Industrial use	Recreation, propagation and management of fish and wildlife	Shellfish propagation and harvesting	Potable water supplies	6
G. Ground-water use of uppermost aquifer	Not used, other sources readily available	Commercial, industrial, or irrigation, very limited other water sources	Drinking water, municipal water available	Drinking water, no municipal water available; commercial, industrial, or irrigation, no other water source available	9
H. Population served by surface water supplies within 3 miles downstream of site	0	1-15	51-1,000	Greater than 1,000	6
I. Population served by aquifer supplies within 3 miles of site	0	1-50	51-1,000	Greater than 1,000	6

II. WASTE CHARACTERISTICS

A-1 Hazardous Waste Quantity

S = Small quantity (5 tons or 20 drums of liquid)
M = Moderate quantity (5 to 20 tons or 21 to 85 drums of liquid)
L = Large quantity (?0 tons or 85 drums of liquid)

A-2 Confidence Level of Information

C = Confirmed confidence level (minimum criteria below)

- o Verbal reports from interviewer (at least 2) or written information from the records
- o Knowledge of types and quantities of wastes generated by shops and other areas on base

S = Suspected confidence level

- o No verbal reports or conflicting verbal reports and no written information from the records
- o Logic based on a knowledge of the types and quantities of hazardous wastes generated at the base, and a history of past waste disposal practices indicate that these wastes were disposed of at a site

A-3 Hazard Rating

Rating Factors	Rating Scale Levels			
	0	1	2	3
Toxicity	Sax's Level 0	Sax's Level 1	Sax's Level 2	Sax's Level 3
Ignitability	Flash point greater than ?00°F	Flash point at 140°F to ?00°F	Flash point at 80°F to 140°F	Flash point less than 80°F
Radioactivity	At or below background levels	1 to 3 times background levels	3 to 5 times background levels	Over 5 times background levels

Use the highest individual rating based on toxicity, ignitability and radioactivity and determine the hazard rating.

Hazard Rating	Points
High (H)	3
Medium (M)	2
Low (L)	1

II. WASTE CHARACTERISTICS--Continued

Waste Characteristics Matrix

Point Rating	Hazardous Waste Quantity	Confidence Level of Information	Hazard Rating
100	L	C	H
80	L	C	M
	M	C	H
70	L	S	H
60	S	C	H
	M	C	M
50	L	S	M
	L	C	L
	M	S	H
	S	C	M
40	S	S	H
	M	S	M
	M	C	L
	L	S	L
30	S	C	L
	M	S	L
	S	S	M
20	S	S	L

Notes:
For a site with more than one hazardous waste, the waste quantities may be added using the following rules:

Confidence Level

- o Confirmed confidence levels (C) can be added.
- o Suspected confidence levels (S) can be added.
- o Confirmed confidence levels cannot be added with suspected confidence levels.

Waste Hazard Rating

- o Wastes with the same hazard rating can be added.
- o Wastes with different hazard ratings can only be added in a downgrade mode, e.g., MCM + SCH = LCM if the total quantity is greater than 20 tons.

Example: Several wastes may be present at a site, each having an MCM designation (60 points). By adding the quantities of each waste, the designation may change to LCM (80 points). In this case, the correct point rating for the waste is 80.

B. Persistence Multiplier for Point Rating

Persistence Criteria	Multiply Point Rating From Part A by the Following
Metals, polycyclic compounds, and halogenated hydrocarbons	1.0
Substituted and other ring compounds	0.9
Straight chain hydrocarbons	0.8
Easily biodegradable compounds	0.4

C. Physical State Multiplier

Physical State	Multiply Point Total From Parts A and B by the Following
Liquid	1.0
Sludge	0.75
Solid	0.50

III. PATHWAYS CATEGORY

A. Evidence of Contamination

Direct evidence is obtained from laboratory analyses of hazardous contaminants present above natural background levels in surface water, ground water, or air. Evidence should confirm that the source of contamination is the site being evaluated.

Indirect evidence might be from visual observation (i.e., leachate), vegetation stress, sludge deposits, presence of taste and odors in drinking water, or reported discharges that cannot be directly confirmed as resulting from the site, but the site is greatly suspected of being a source of contamination.

B-1 Potential for Surface Water Contamination

Rating Factors	Rating Scale Levels 0	1	2	3	Multiplier
Distance to nearest surface water (includes drainage ditches and storm sewers)	Greater than 1 mile	2,001 feet to 1 mile	501 feet to 2,000 feet	0 to 500 feet	8
Net precipitation	Less than -10 inches	-10 to +5 inches	+5 to +20 inches	Greater than +20 inches	6
Surface erosion	None	Slight	Moderate	Severe	8
Surface permeability	0% to 15% clay ($>10^{-2}$ cm/sec)	15% to 30% clay (10^{-2} to 10^{-4} cm/sec)	30% to 50% clay (10^{-4} to 10^{-6} cm/sec)	Greater than 50% clay ($>10^{-6}$ cm/sec)	6
Rainfall intensity based on 1-year 24-hour rainfall (Thunderstorms)	<1.0 inch 0-5 0	1.0 to 2.0 inches 6-35 30	2.1 to 3.0 inches 36-49 60	>3.0 inches >50 100	8

B-2 Potential for Flooding

Floodplain	Beyond 100-year floodplain	In 100-year floodplain	In 10-year floodplain	Floods annually	1

B-3 Potential for Ground-Water Contamination

Depth to ground water	Greater than 500 feet	50 to 500 feet	11 to 50 feet	0 to 10 feet	8
Net precipitation	Less than -10 inches	-10 to +5 inches	+5 to + 20 inches	Greater than +20 inches	6
Soil permeability	Greater than 50% clay ($>10^{-6}$ cm/sec)	30% to 50% clay (10^{-4} to 10^{-6} cm/sec)	15% to 30% clay (10^{-2} to 10^{-4} cm/sec)	0% to 15% clay ($<10^{-2}$ cm/sec)	8

B-3 Potential for Ground-Water Contamination--Continued

Rating Factors	Rating Scale Levels 0	1	2	3	Multiplier
Subsurface flows	Bottom of site greater than 5 feet above high ground-water level	Bottom of site occasionally submerged	Bottom of site frequently submerged	Bottom of site located below mean ground-water level	8
Direct access to ground water (through faults, fractures, faulty well casings, subsidence, fissures, etc.)	No evidence of risk	Low risk	Moderate risk	High risk	8

IV. WASTE MANAGEMENT PRACTICES CATEGORY

A. This category adjusts the total risk as determined from the receptors, pathways, and waste characteristics categories for waste management practices and engineering controls designed to reduce this risk. The total risk is determined by first averaging the receptors, pathways, and waste characteristics subscores.

B. Waste Management Practices Factor

The following multipliers are then applied to the total risk points (from A):

Waste Management Practice	Multiplier
No containment	1.0
Limited containment	0.95
Fully contained and in full compliance	0.10

Guidelines for fully contained:

Landfills:

- o Clay cap or other impermeable cover
- o Leachate collection system
- o Liners in good condition
- o Adequate monitoring wells

Surface Impoundments:

- o Liners in good condition
- o Sound dikes and adequate freeboard
- o Adequate monitoring wells

Spills:

- o Quick spill cleanup action taken
- o Contaminated soil removed
- o Soil and/or water samples confirm total cleanup of the spill

Fire Protection Training Areas:

- o Concrete surface and berms
- o Oil/water separator for pretreatment of runoff
- o Effluent from oil/water separator to treatment plant

General Note: If data are not available or known to be complete the factor ratings under items I-A through I, III-B-1, or III-6-3, then leave blank for calculation of factor score and maximum possible score.

1. Surface water migration

Distance to nearest surface water	0	8	0	24
Net precipitation	3	6	18	18
Surface erosion	0	8	0	24
Surface permeability	1	6	6	18
Rainfall intensity	1	8	8	24
		Subtotals	32	108

Subscore (100 X factor score subtotal/maximum score subtotal) 30

2. Flooding

	1	1	1	3

Subscore (100 X factor score/3) 33

3. Ground water migration

Depth to ground water	2	8	16	24
Net precipitation	2	6	12	18
Soil permeability	2	8	16	24
Subsurface flows	0	8	0	24
Direct access to ground water	0	8	0	24
		Subtotals	44	114

Subscore (100 X factor score subtotal/maximum score subtotal) 39

C. Highest pathway subscore.

Enter the highest subscore value from A, B-1, B-2 or B-3 above.

Pathways Subscore 39

IV. WASTE MANAGEMENT PRACTICES

A. Average the three subscores for receptors, waste characteristics, and pathways.

Receptors	32
Waste Characteristics	50
Pathways	39
Total 121 divided by 3 =	40
	Gross Total Score

B. Apply factor for waste containment from waste management practices

Gross Total Score X Waste Management Practices Factor = Final Score

40 X 1.0 = 40

HAZARDOUS ASSESSMENT RATING FORM

NAME OF SITE Site No. 7, Burn Pit Area

LOCATION Carl Ave

DATE OF OPERATION OR OCCURRENCE 1957-1978

OWNER/OPERATOR Portland International Airport Air National Guard Installation, Portland, Oregon

COMMENTS/DESCRIPTION

SITE RATED BY Hazardous Material Technical Center

I. RECEPTORS

Rating Factor	Factor Rating (0-3)	Multiplier	Factor Score	Maximum Possible Score
A. Population within 1,000 feet of site	0	4	0	12
B. Distance to nearest well	2	10	20	30
C. Land use/zoning within 1 mile radius	2	3	6	9
D. Distance to installation boundary	1	6	6	18
E. Critical environments within 1 mile radius of site	0	10	0	30
F. Water quality of nearest surface water body	1	6	6	18
G. Ground water use of uppermost aquifer	1	9	9	27
H. Population served by surface water supply within 3 miles downstream of site	0	6	0	18
I. Population served by ground-water supply within 3 miles of site	0	6	0	18
		Subtotals	57	180

Receptors subscore (100 X factor score subtotal/maximum score subtotal) 32

II. WASTE CHARACTERISTICS

A. Select the factor score based on the estimated quantity, the degree of hazard, and the confidence level of the information.

1. Waste quantity (S = small, M = medium, L = large) L
2. Confidence level (C = confirmed, S = suspected) C
3. Hazard rating (H = high, M = medium, L = low) M

Factor Subscore A (from 20 to 100 based on factor score matrix) 80

B. Apply persistance factor
Factor Subscore A X Persistence Factor = Subscore B

1.0 X 80 = 80

C. Apply physical state multiplier

Subscore B X Physical State Multiplier = Waste Characteristics Subscore

1.0 X 80 = 80

III. PATHWAYS

Rating Factor	Factor Rating (0-3)	Multiplier	Factor Score	Maximum Possible Score

A. If there is evidence of migration of hazardous contaminants, assign maximum factor subscore of 100 points for direct evidence or 80 points for indirect evidence. If direct evidence exists then proceed to C. If no evidence or indirect evidence exists, proceed to B.

Subscore 0

B. Rate the migration potential for 3 potential pathways: surface water migration, flooding, and ground-water migration. Select the highest rating, and proceed to C.

1. Surface water migration

Distance to nearest surface water	0	8	0	24
Net precipitation	3	6	18	18
Surface erosion	0	8	0	24
Surface permeability	1	6	6	18
Rainfall intensity	1	8	8	24
		Subtotals	32	108

Subscore (100 X factor score subtotal/maximum score subtotal) 30

2. Flooding

Flooding	1	1	1	3

Subscore (100 X factor score/3) 33

3. Ground water migration

Depth to ground water	2	8	16	24
Net precipitation	2	6	12	18
Soil permeability	2	8	16	24
Subsurface flows	0	8	0	24
Direct access to ground water	0	8	0	24
		Subtotals	44	114

Subscore (100 X factor score subtotal/maximum score subtotal) 39

C. Highest pathway subscore.

Enter the highest subscore value from A, B-1, B-2 or B-3 above.

Pathways Subscore 39

IV. WASTE MANAGEMENT PRACTICES

A. Average the three subscores for receptors, waste characteristics, and pathways.

Receptors	32
Waste Characteristics	80
Pathways	39
Total 151 divided by 3 =	50
	Gross Total Score

B. Apply factor for waste containment from waste management practices

Gross Total Score X Waste Management Practices Factor = Final Score

50 X 1.0 = 50

APPENDIX D
ANALYSIS OF OIL SAMPLES
NORTH BEND AIR NATIONAL GUARD STATION

Environmental Laboratory

Date: October 1, 1984

Invoice No.: C32375

Subject: Analysis of oil samples from the Oregon Air National Guard, North Bend, Oregon. The samples were received September 27, 1984, and assigned reference Nos. 4918-4919. Values are given as ug/g (parts per million).

Sample ID	PCB's
East transformer	BMDL
Center transformer	BMDL

Notes: BMDL indicates below method detection limit
Method detection limit = 5 ppm

All tests are performed in accordance with current Environmental Protection Agency guidelines as published in the Federal Register.

The information shown on this sheet is test data only and no interpretation is intended or implied.

Samples will be retained 30 days unless otherwise requested.

Reported by: _____

APPENDIX E
RESUMES OF SEARCH TEAM MEMBERS

JODY C. MOONEY

EDUCATION

B.S., chemistry, University of Maryland, 1975

EXPERIENCE

Eleven years of experience in hazardous waste and environmental science fields. Experience includes research in organic chemistry (polythiol-ene) and management for a treatment/storage/disposal (TSD) facility. As an associate chemist, performed analysis of inorganic and organic parameters of wastewater samples. Has extensive knowledge of state and federal DOT, RCRA and TSCA regulations on hazardous waste.

EMPLOYMENT

Dynamac Corporation (1986-present): Staff Scientist

Responsibilities include site surveys and records searches for the Phase I portion of the Installation Restoration Program for the Air National Guard. Efforts include risk assessment, site prioritization and remedial action recommendations. Participated in the evaluation of a wastewater treatment plant.

Transviron Incorporated (1984-1985): Environmental Scientist

Prepared proposals for various remedial investigations and feasibility studies (including NUS subcontract award) and supervised field activities relating to investigations and cleanups. Also responsible for hazardous waste management programs set up for commercial clients.

Atlantic Coast Environmental, Inc. (1983-1984): Director of Chemical Services

Planned, directed, and controlled the activities of two operation managers and one technical supervisor for a TSD facility. Supervised facility laboratory operation and assisted clients in chemical disposal problems. Chemical advisor to emergency coordinator of chemical spills.

Browning-Ferris Industries, Inc. (1982-1983): Chemist

Responsible for assuring that the facility (Quarantine Road) operated in compliance with state, local, and federal regulations. Managed the East Coast Regional Environmental Laboratory. Developed field procedures for groundwater monitoring program. Responsible for sampling analysis, treatment, and bringing six lagoons into compliance for discharge with NPDES permit.

Hittman Associates, Inc. (1980-1982): Associate Chemist

Performed analysis of inorganic and organic parameters of wastewater samples. Organized supplies and sample shipment for Exxon Donor Solvent Program. As project scientist, conducted a wastewater study at Bush River, Maryland. Laboratory representative on the safety committee.

Alcolac, Inc. (1979-1980): Quality Control Laboratory Technician

W.R. Grace, Inc., Washington Research Center (1975-1978): Research Technician (Organic)

PROFESSIONAL AFFILIATIONS

The American Chemical Society -- Maryland Local Section

TIMOTHY N. GARDNER

Environmental Scientist

EDUCATION

M.A., Environmental Biology, Hood College
B.S., Forestry/Resource Management, West Virginia University

EXPERIENCE

Mr. Gardner has five years of technical experience in environmental control and research, with emphasis on risk assessment, chemical safety, radiation safety, hazardous waste management (chemical and radiologic), and activated carbon filtration research. His past responsibilities include site risk assessment, chemical and radioactive waste pickup and storage for disposal at a large cancer research facility, and chemical and radioactive spill control, as well as safety surveys and technical assistance in activated carbon desorption research.

EMPLOYMENT

Dynamac Corporation (1984-Present): Staff Scientist

At Dynamac, Mr. Gardner's responsibilities include site surveys and records searches for the Phase I portion of the Installation Restoration Program (IRP) for various Air National Guard Bases. Efforts include risk assessment, site prioritization, and remedial action recommendations. He has also been a contributing author for a closure-post closure plan for a hazardous waste landfill at Clovis AFB, plans and specifications for the removal of asbestos at several Air Force White Alice sites in Alaska, and the update and revision of a DLA regulation for "Disposal of Unwanted Radioactive Material."

NCI-Frederick Cancer Research Facility (1981-1984): Lab Technician

Mr. Gardner worked in radiation and chemical safety as well as environmental research. His responsibilities included monitoring personal and environmental air quality at work areas where free iodinations occurred, monitoring work areas and equipment for isotope contamination, periodic surveys to monitor compliance with NRC safety regulations, isotope inventory control, transfer of isotopes between licenses, and periodic calibration and maintenance of survey instruments. He was also responsible for radioactive and chemical waste pickup and storage for disposal, and served as an advisor for safety-related matters pertinent to radiation and radioactive waste, chemical safety, and industrial hygiene. In the environmental research division, he was involved in activated carbon desorption studies involving the use of analytic laboratory equipment.

NATASHA M. BROCK

EDUCATION

Graduate work, civil/environmental engineering, University of Maryland, 1987-present
Graduate work, civil/environmental engineering, University of Delaware, 1985-1986
B.S. (cum laude), environmental science, University of the District of Columbia, 1984
Undergraduate work, biology, The American University, 1978-1980

CERTIFICATION

Health & Safety Training Level C

EXPERIENCE

Three years' experience in the environmental and hazardous waste field. Work performed includes remedial investigations/feasibility studies, RCRA facility assessments, comprehensive monitoring evaluations, and remedial facility investigations. Helped develop and test biological and chemical processes used in minimization of hazardous and sanitary waste generation. Researched multiple substrate degradation using aerobic and anaerobic organisms.

EMPLOYMENT

Dynamac Corporation (1987-present): Environmental Scientist

In working for Dynamac's Hazardous Materials Technical Center (HMTC), performs Preliminary Assessments, Remedial Investigations and Feasibility Studies (PA/RI/FS) under the Air National Guard Installation Restoration Program. Specifically involved in determining rates and extent of contamination, recommending groundwater monitoring procedures, and soil sampling and analysis procedures. In the process of preparing standard operating procedure manuals for quick remedial response to site spills and releases, and PA/RI/FS.

C.C. Johnson & Malhotra, P.C. (1986-1987): Environmental Scientist

Involved as part of a team in performing Remedial Investigations/Feasibility Studies (RI/FS) for EPA Regions I and IV under Resource Conservation and Recovery Act (RCRA) work assignments for REM II projects. Participated on a team involved in RCRA Facility Assessments (RFAs), Comprehensive Monitoring Evaluations (CMEs), and Remedial Facility Investigations (RFIs) for EPA work assignments under RCRA for REM III projects in Regions I and IV. Work included solo oversight observations of field sampling and facility inspections. Additional responsibilities included promotion work, graphic layout, data entry-quality check for various projects. Certified Health & Safety Training Level C.

Work Force Temporary Services (1985-1986): Research Scientist

In working for DuPont's Engineering Test Center, helped in the development and testing of laboratory-scale biological and chemical processes for a division whose main purpose was to reduce the amount of hazardous waste generated. Also worked for Hercules, Inc., with a group involved in polymer use for wastewater treatment for clients in various industrial fields. Specifically involved in product consultation, troubleshooting, and product development.

National Oceanic and Atmospheric Administration (1982-1984): Research Assistant

Involved with an information gathering and distribution center of weather impacts worldwide. Specifically involved in data collection, distribution of data to clients, assessment production and special reports.

SECTION 1.0 INTRODUCTION

The Department of Defense (DoD) has developed a program to identify and evaluate sites on DoD property where contamination may be present due to past spills or hazardous waste disposal practices. This program is the Installation Restoration Program (IRP), and its purpose is to confirm the existence or absence of suspected contamination and to control hazards to health, welfare, or the environment that may result from their presence. As part of this program, Headquarters Air National Guard (HQ ANG/CEVR) has entered into an interagency agreement (IAG) No. 1489-1489-A1 with the Department of Energy (DOE) under which DOE will provide technical assistance for the implementation of the ANG/CEVR IRP and related activities. Lockheed Martin Energy Systems' Hazardous Waste Remedial Actions Program (HAZWRAP) has been assigned the responsibility for managing this effort under the IAG.

This Remedial Investigation (RI) Work Plan (WP) was developed as part of the IRP being conducted at the 142nd Fighter Group (FG), hereinafter referred to as the Base, located at Portland International Airport (PIA) (Figure 1.1). The purpose of this WP is to present overall and site-specific technical, and management approaches to use for completing the IRP for sites designated for further study at the Base.

The ten IRP sites, shown in Figure 1.2, addressed by this RI include:

IRP Site No. 1:	Central Hazardous Waste Storage Area
IRP Site No. 2:	Civil Engineering Hazardous Material Storage Area
IRP Site No. 3:	Hush House Area
IRP Site No. 4:	Main Drainage Ditch
IRP Site No. 5:	AGE Maintenance Shop
IRP Site No. 7:	Burn Pit Area
IRP Site No. 8:	Sanitary Landfill
IRP Site No. 9:	Petroleum, Oil, and Lubricant (POL) Facility
IRP Site No. 10:	Equipment Washrack
IRP Site No. 11:	Washrack West of Building 250

In addition to the above referenced sites, Base background information, regarding soil and groundwater, will be collected by installing monitoring wells and soil borings.

DECEMBER 1995

1.1 PROJECT OBJECTIVES AND SCOPE

Based on the results of the Site Investigation (SI) performed by Science Applications International, Inc. (SAIC) in 1989, ten sites were recommended for further investigation to be conducted by this RI. The purposes of the RI are to:

- Evaluate the nature of contamination;
- Evaluate the vertical and horizontal extent of contamination in soils and groundwater;
- Gather and evaluate the necessary data to support a Feasibility Study (FS) or a Removal Action (RA) as appropriate;
- Prepare Decision Documents (DDs) supporting No Further Action (NFA) as appropriate;
- Support a screening (human health and ecological) risk assessment;
- Identify pathways and potential exposure routes for the screening risk assessment; and
- Characterize site and Base hydrogeology and geology.

The scope of the RI activities addressed by this WP shall include, but not be limited to:

- Soil and groundwater sampling with direct push technology;
- On-site laboratory analysis;
- Off-site laboratory confirmation;
- Electronic data management system for receipt and interpretation of investigation results; and
- Report preparation.

One of the objectives of the RI is to use an on-site analytical laboratory to help provide data about the sites and make real-time decisions regarding the progress of the field investigation. The process will make the field effort more efficient and minimize the time spent waiting on analytical results. Using this process should help complete the remedial investigation field effort in one mobilization and ultimately save on costs. The real-time data will be evaluated and, if necessary, the field program can be modified (within the constraints of available equipment, time, and monies) to help achieve the project objectives.

One of the data quality objectives includes performing analytical procedures and obtaining results that are accurate, precise, and defensible. The field laboratory will be designed and setup to meet these same project data quality objectives; the only difference is it is not a fixed-base laboratory.

1.2 INSTALLATION RESTORATION PROGRAM (IRP) DESCRIPTION

The United States Air Force (USAF), including HQ ANG/CEVR, has engaged in a wide variety of operations dealing with toxic and hazardous materials due to its primary mission in defense of the United States. In order to address this problem, the Defense Environmental Restoration Program (DERP) was established in 1984 to promote and coordinate efforts for the evaluation and clean-up of contamination at DoD installations. On January 23, 1987, Presidential Executive Order (EO) 12580 was issued which assigned the responsibility of carrying out the DERP to the Secretary of Defense. As a result, the IRP was established under the DERP to identify, evaluate, and mitigate past hazardous material disposal sites on DoD properties.

The IRP is focused on conducting remedial measures (as necessary) associated with past DoD activities to ensure that threats to public health are eliminated and to restore natural resources for future use. Activities under the IRP are conducted in phases that parallel the requirements of the U. S. Environmental Protection Agency (USEPA) under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the National Oil and Hazardous Substances Pollution Contingency Plan (NCP).

The HQ ANG/CEVR, located at Andrews Air Force Base, Maryland, has ultimate responsibility for the IRP at installations located throughout the country.

1.3 GENERAL INVESTIGATION APPROACH

This RI provides a description of the activities proposed to quantify the horizontal and vertical extent, and the magnitude and extent of contamination at IRP Site Nos. 1 through 5 and 7 through 11, as well as the possible migration of any of the contaminants from the sites. Sediments, surface and subsurface soils, and surface and ground water data will be collected and evaluated to facilitate accomplishing these objectives. In addition, a screening risk assessment will be performed to determine the likelihood of adverse human health and ecological effects, which control decisions about the need for cleanup methods to be used.

1.4 WORK PLAN STRUCTURE

The Work Plan provides a description of the activities proposed for the RI and is organized into fifteen sections and four appendices described below.

Section 1.0 **Introduction**, provides the purpose, scope and structure of the investigation, summarizes the IRP Program, and describes the general investigation approach.

Section 2.0 **Project Management Approach**, describes the project management organization and approach, and the quality and data management procedures proposed for the execution of the project.

Section 3.0 **Facility Background Information**, provides a description and history of the Base, and site-specific information of the ten sites addressed by this investigation. A description of previous IRP investigation activities is also provided.

Section 4.0 **Environmental Setting**, provides pertinent physical details about the setting of the Base.

Section 5.0 **Permits**, describes the permitting process required to perform the field activities for the project.

Section 6.0 **Investigation Approach**, provides the objectives and Data Quality Objectives (DQOs) which apply to the project, as well as the sampling strategy and approach that was used to meet these objectives.

Section 7.0 **Field Investigation Procedures**, describes the field procedures to be utilized during the drilling activities, geophysical surveys, and microwell/monitoring well installation, required for the investigation.

Section 8.0 **Sample Collection Procedures**, describes the sampling procedures to be utilized during the field activities required for the investigation.

Section 9.0 **Summary of Potential ARARs**, provides the Applicable or Relevant and Appropriate Requirements (ARARs) which may potentially impact the project investigative decision process.

Section 10.0 **Risk Assessment**, describes the procedures for conducting a screening risk assessment at each of the sites.

Section 11.0 **Equipment Decontamination Procedures**, describes the equipment decontamination procedures to be utilized during the field activities required for the investigation.

Section 12.0 **Borehole Abandonment Procedures**, describes the borehole abandonment procedures to be utilized during the field activities required for the investigation.

Section 13.0 **Investigative Derived Waste Management**, (IDW) provides the procedures proposed for the handling and disposal of all investigative derived waste produced during field activities.

Section 14.0 **Project Schedules and Deliverables**, describes the proposed project time frame for accomplishing the required RI, the proposed meetings, and the project deliverables.

Section 15.0 **References**, provides a listing of references used in preparation of the RI Work Plan.

Appendix A Presents the Health and Safety Plan (HSP) developed for operations at the Base.

Appendix B Presents the Quality Assurance Project Plan (QAPP), which describes the overall policies, specific quality assurance and quality control requirements, procedures, responsibilities, chain-of-custody, laboratory analyses, and documentation that will be employed during the RI.

Appendix C Presents the Standard Operating Procedures (SOPs) referenced in the RI WP.

Appendix D Presents Material Safety Data Sheets (MSDS) for chemicals of concern identified at the Base.

Appendix E Presents the USEPA Region III risked-based concentrations (RBC) table that states reference doses and carcinogenic potency slopes for 600 chemicals. These references will be used as a baseline during the screening risk assessment.

Appendix F Presents the Field Forms to be utilized during the RI field activities.

SECTION 2.0 PROJECT MANAGEMENT APPROACH

The successful execution of this project lies in a strong, qualified project team. Accordingly, the subcontractor will establish an experienced team of professionals who have performed similar government and industrial activities to be a part of the project team. The project team will be specified and provided to the HAZWRAP Project Manager (PM) as part of the Business and Technical Proposal.

2.1 PROJECT MANAGEMENT ORGANIZATION

The project will be managed and executed by personnel selected by the subcontractor who will ensure that the objectives of the RI are met as defined in the final as negotiated contract. Drilling, analytical laboratory, geophysical survey, and well and boring location surveying support will be provided by subtier subcontractor firms experienced in performing their specific assigned tasks, and which possess the required permits, licenses and accreditations necessary to work in Oregon. The responsibilities of subcontractor personnel who are considered key project personnel are described below:

The Program Manager will be administratively responsible for coordinating resources and priorities for the project and for maintaining an open line of communication with the HAZWRAP Project Manager. Communications with HQ ANG/CEVR will be through the HAZWRAP Project Manager.

The Project Manager (PM) will serve as the principle point of contact with HAZWRAP and the Base. The Project Manager will direct the project team, including field operations, and coordinate all subtier subcontractor support.

The Field Team Leader (FTL) will directly supervise all field operations. Responsibilities will include planning, conducting, and overseeing all field personnel, including subtier subcontractors.

The Quality Assurance/Quality Control (QA/QC) Manager will be responsible for developing standardized quality assurance procedures for this project and for ensuring that effective procedures and controls are implemented to achieve a high level of project accuracy.

The Site Safety Officer (SSO) will be responsible for the safety of all on-site personnel and operations and evaluating any potential unsafe conditions for on-site personnel.

The Data Management and Analytical Data Evaluation Manager (DEM) will be responsible for evaluation of analytical data and to ensure that high quality data is collected. Responsibilities will also include ensuring that proper data tracking and management are implemented to achieve a high level of project data accuracy.

2.2 PROJECT PROCEDURES

An open line of communication will be maintained between the PM and the project team to ensure that all project objectives are met. Samples will be properly collected and identified, with verifiable sample custody being an integral part of the field work. A member of the field team will maintain a bound field logbook in which details of that team's daily field activities will be recorded. All information pertinent to field observations, screening, and sampling will be written legibly in indelible ink. Additional information may be recorded on field forms (i.e., well completion form, sample collection form, etc.) at the discretion of the field team(s). In addition, a Project Logbook will be maintained by the FTL, which will be updated at the end of each day's activities, to compile and detail the activities of all the field crews' accomplishments for that day. The Project Logbook, the crews individual logbooks, and the individual field forms, will be maintained in the project file. During the RI field activities, the following information will also be prepared on a weekly basis and be reported to all field personnel and the HAZWRAP PM:

- Weekly highlights of field findings and activities;
- Cost avoidance procedures; and
- Summary of weekly success/failure and/or lessons learned.

All field activities are further detailed in, and will be carried out in accordance with, the HSP, the QAPP, and the subcontractor's SOPs, presented in Appendices A, B, and C, respectively. The RI project schedule will be included as part of the Technical Business Proposal. A conceptual model for Project RI approach from work plan preparation to preparation of final report is presented in Figure 2.1.

2.3 QUALITY MANAGEMENT

Quality management is the process of ensuring that the proper, legally defensible data is collected. For this project that means ensuring that the RI will provide the information necessary to proceed toward closure. To achieve this goal, all problems encountered during field work will be reported to the FTL, who will contact the subcontractor PM and the HAZWRAP PM.

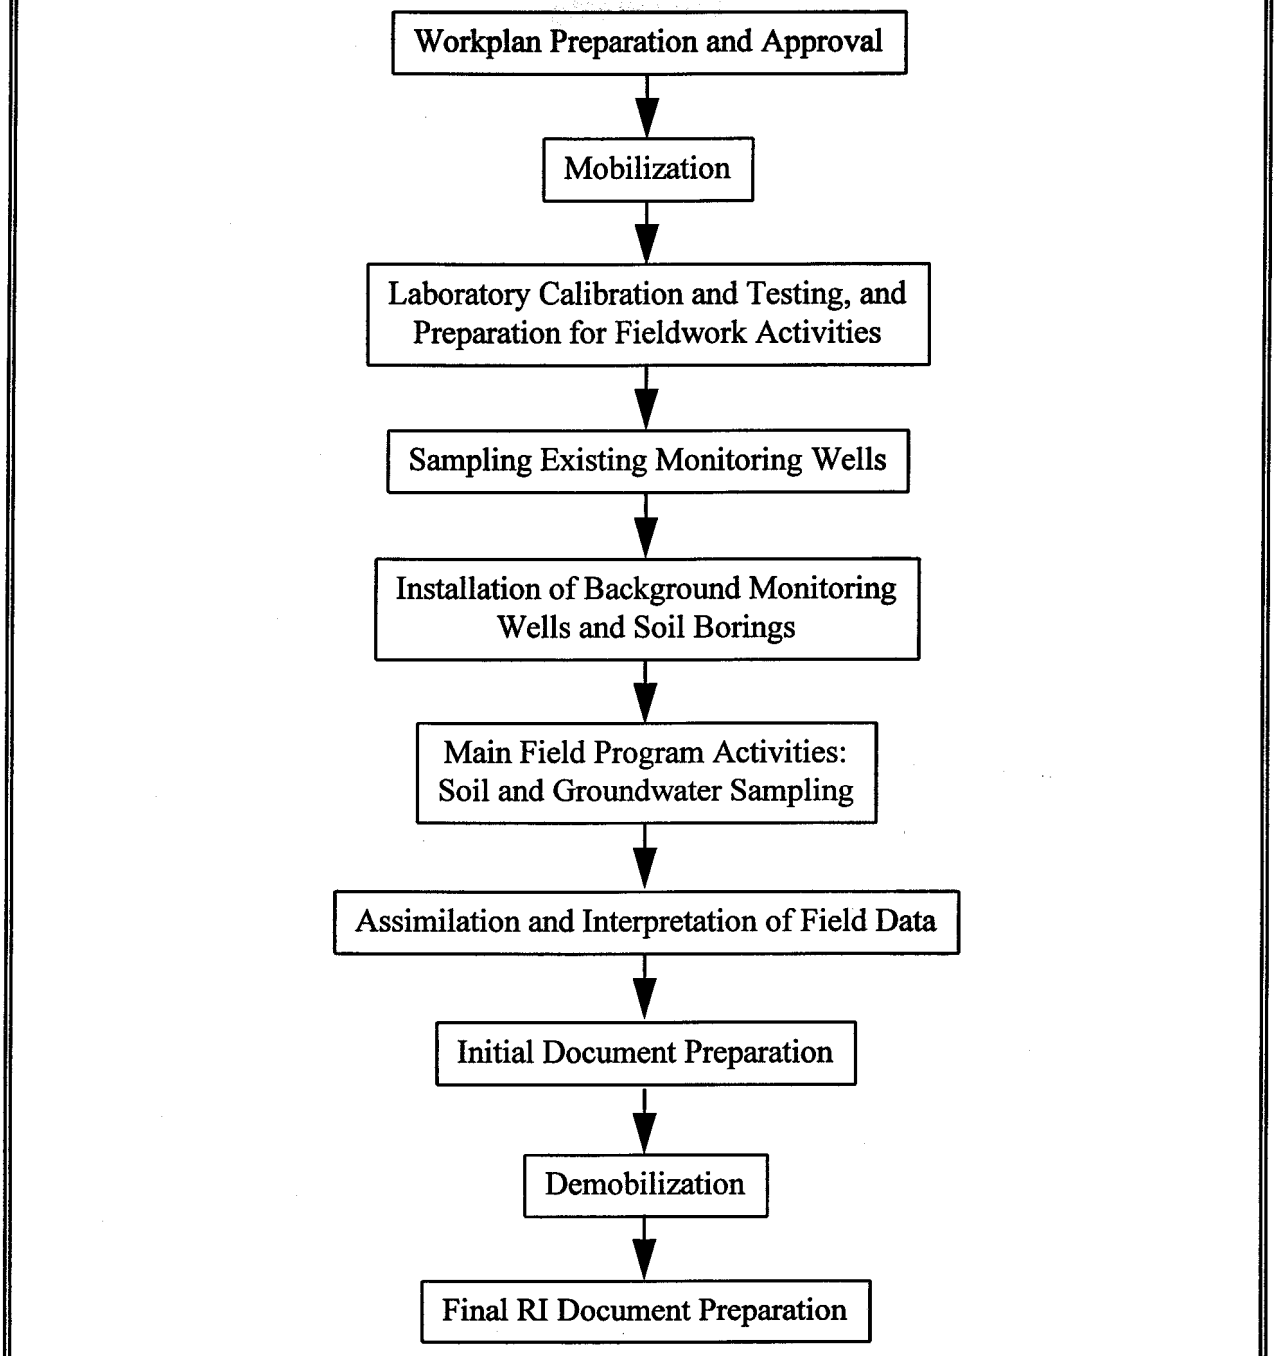

Figure 2.1	**CONCEPTUAL MODEL FOR PROJECT RI APPROACH** **142nd Fighter Group, Oregon Air National Guard** **Portland International Airport, Portland, Oregon**	**OPTECH** **Operational Technologies** **CORPORATION**

Immediate corrective actions will be taken anytime it is deemed necessary. The contractor's QA/QC Manager will be responsible for ensuring all QC procedures are followed for the project. Quality control procedures are further detailed in, and will be carried out in accordance with, the QAPP presented in Appendix B.

2.4 SUBCONTRACT MANAGEMENT

The subcontractor is totally and solely responsible for the cost, schedule, and quality of all work performed under the final negotiated contract, including the work of subtier subcontractors. The project subcontractor will hire subtier subcontractors for the drilling, analytical laboratory, geophysical survey, and well and boring location surveying support. These subcontractors will support the project contractor's efforts at the Base and will be selected through a fair and competitive procurement process. The Field Team Leader will maintain oversight of the subcontractors' completion of specified tasks with respect to technical performance, quality, and adherence to cost and schedule. All subcontractor activity will be in compliance with the HSP, QAPP, and SOPs, presented in Appendices A through C.

2.5 DATA MANAGEMENT

2.5.1 Electronic Data Management

An integrated data management system, using Access™ database, Window's Paintbrush™ software, and a word processing program integrated with Real-Time Interpretation System (R-TIS) software modified for this RI, will be used to compile field laboratory results, field survey data and fixed-base laboratory data into a useable format and produce real-time interpretation of site conditions. The system will be capable of querying the database by analyte, parameter, site, concentrations, matrix, and sample quantities and generating two dimensional maps of each site for visualization of data measurements.

The Access database fields will be modified to contain all analytical methods, complete analyte lists, and appropriate action levels for this RI. The Access database will contain all sample analysis information discussed in Section 10 of the QAPP. Additional information contained within the database will include, but is not limited to:

- Sample X, Y, and Z coordinates;
- Established Project Action Goals;

- A brief description of the sample;
- Where the sample was collected;
- Surface elevation (if applicable);
- Top of casing (if applicable);
- Top of well screen (if applicable);
- Bottom of well screen (if applicable);
- Water level (if applicable);
- Total depth (if applicable) for monitoring well/microwell and soil boring; and
- A brief description of the site.

The DEM will be responsible for the daily maintenance and updating of the database. The PM or a designee will be responsible for oversight of the descriptions included in the database, queries, maps, and reports generated from the R-TIS system. The DEM will be responsible for verifying all measurement entries against the hard copy data, updating the database on a daily basis, and performing daily data backups. The backup data will be stored in a separate location. The analytical laboratories will be responsible for delivering electronic information concurrently with the hard copy results on the sample analysis to the database manager for entry into the database. The DEM is responsible for oversight of database management and laboratory coordination. Data review for analytical compliance is discussed in Sections 9.0 and 10.0 of the QAPP. The DEM will be responsible only for the correctness of the entry of data, not the integrity of the values.

2.5.2 Hard Copy Data Management

The field laboratory must provide hard copies of sample results to the contractor no later than 48 hours after samples are received at the field laboratory. Hard copies of sample results must be provided by the fixed-base laboratory no later than seven days after sample receipt. Complete data packages from the field and fixed-base laboratories that contain all deliverables listed in Tables 10.1 and 10.2 of Appendix B (QAPP) must be received by the contractor within thirty days of sample receipt by the laboratory. All sample results and data packages will be reviewed by the analytical laboratories for correctness and completeness prior to submitting data to the contractor. Evidence of this review must be provided with the data. The subcontractor is responsible for the quality of data generated by both field and fixed-base laboratories and will monitor analytical performance of both laboratories on a daily basis to ensure compliance with analytical methods, the QAPP, the analytical subtier subcontract, and HAZWRAP's DOE/HWP-65/R1. Analytical

data from the field and fixed-base laboratories will be validated according to procedures specified in Section 10.0 of the QAPP.

SECTION 3.0 FACILITY BACKGROUND INFORMATION

3.1 FACILITY DESCRIPTION AND HISTORY

The Base is located on the south side of the PIA in Portland, Oregon. The PIA is located northeast of the city between the Columbia River to the north and the Columbia Slough to the south. The Base occupies approximately 245 acres of land leased from the City of Portland Port Authority.

The Base is bordered on the west by Riverside Country Club and the Peninsula Drainage Canal, and on the north by the PIA. The areas south and east of the Base are designated residential, industrial, and commercial. All IRP sites are located within the confines of the Base, except IRP Site No. 7, the former Burn Pit Area which straddles the southeast Base boundary.

The 142nd FG was opened in 1941 and functioned as an Army Air Base until 1945. Following World War II, the Base was converted to an Air National Guard facility and has maintained that status to the present time. The major support operations performed at the Base that use and dispose of hazardous wastes/hazardous materials include aircraft maintenance, ground maintenance, petroleum, oil, and lubricants (POL) management, and facilities maintenance. These activities generate varying quantities of waste oils, recovered fuels, spent cleaners, solvents, and acids.

3.1.1 Previous IRP Investigation Activities and Documentation

In 1987, under the USAF IRP as implemented by the Air National Guard, a Phase I Record Search was completed and recorded as part of the Preliminary Assessment (PA) Hazardous Materials Training Center (HMTC) (1987). The PA investigation included an on-site visit including interviews with past and present Base employees; the acquisition and analysis of pertinent information and records on the Base's hazardous materials use and waste generation and disposal practices; and the analysis of available geologic, hydrologic, meteorological, and environmental data from federal, state, and local agencies.

As a result, investigators evaluated eight sites on the Base (IRP Site Nos.1 through 8) and ranked six of them in accordance to the USAF Hazardous Assessment Rating Methodology (HARM) protocol. The eight sites evaluated during the PA are as follows:

IRP Site No.1 - Central Hazardous Waste Storage Area
IRP Site No.2 - Civil Engineering Hazardous Material Storage Area
IRP Site No.3 - Hush House Area
IRP Site No.4 - Main Drainage Ditch
IRP Site No.5 - AGE Maintenance Shop
IRP Site No.6 - Washrack West of Building 1355
IRP Site No.7 - Burn Pit Area
IRP Site No.8 - Sanitary Landfill

IRP Site No. 6 was recommended for no further action, and thus, it was not scored during the HARM process. Due to the lack of sufficient information at IRP Site No. 8, this site was not considered in the HARM process.

Subsequent to the PA, field sampling was conducted at selected locations on the Base by R.N. Smith Associates, in 1987 (IRP Site No.4) and by SRH Associates, Inc. in October, 1988 (IRP Site No. 3).

In December of 1988, the Oregon Air National Guard (OANG) reported a Underground Storage Tank (UST) leak at the POL Facility (IRP Site No. 9) to the Oregon Department of Environmental Quality (ODEQ).

In 1989, an SI of the IRP sites identified in the PA (IRP Site Nos. 1 through 5, 7, and 8) as requiring further investigation was implemented by SAIC under a contract with HAZWRAP. The results of the SI are summarized in the Site Investigation Report - Volumes I and II (SAIC, 1991). The SI Report recommended the preparation of a no further action decision document for IRP Site No. 1 soil, IRP Site No. 3, and IRP Site No. 8. Due to the presence of contaminants in soil and groundwater and the lack of sufficient data to completely characterize the sites, further investigation was recommended for IRP Site No. 1 groundwater, IRP Site No. 2, IRP Site No. 4, IRP Site No. 5, and IRP Site No. 7. Based on the previous analytical results from samples collected at IRP Site Nos. 10 and 11 by Base personnel, these two sites were also recommended for further investigation during the RI.

3.1.2 Other Investigation Activities

In April 1995, a Regional Information Document (RID) was prepared by Foster Wheeler Environmental Corporation under a contract with HAZWRAP. The purpose of the RID was to

summarize and evaluate the available information and relate this information to the RI activities to be conducted at the Base and the environmental concerns regarding the Columbia River and the Columbia Slough.

3.2 IRP SITE DESCRIPTIONS

3.2.1 IRP Site No. 1 - Central Hazardous Waste Storage Area

The Central Hazardous Waste Storage Area (IRP Site No. 1) is located on the north side of Building (Bldg.) 1131 depicted on Figure 3.1. IRP Site No. 1 was used as a waste storage area and did not have a containment structure (SAIC, 1991). The surrounding area north of the site is grassy and unpaved. Hampshire Boulevard dissects part of the site on the east side. O'Conner Way borders the site on the north.

Bldg. 1131 is a wooden structure and is currently used as a lawn maintenance equipment storage shed. The asphalt area on the west side of the building is used for temporary storage of electrical transformers and other miscellaneous equipment.

Underground utility lines, including a new storm sewer, are along the eastern portion of the site. Surface water drains off-site through storm drain inlets, located on the north and west sides of the site, into the drainage ditch along Hannis Street and eventually pumps into the Columbia Slough.

3.2.1.1 Waste Disposal History and Previous Investigation

Starting in 1970, IRP Site No. 1 was used as a waste storage area of miscellaneous wastes, including 55-gallon drums of waste oil, solvent, fuels, shop wastes, electrical transformers and capacitors.

Although no spills were reported in the PA Report, stained soils have been observed at the site during the SI (SAIC, 1991).

Subsequent to the PA, four composite soil samples collected from a test pit excavation (Figure 3.1) at the site detected high concentrations of total petroleum hydrocarbons (TPH), 594 milligrams per kilogram (mg/kg) and 12 mg/kg at a depth of 0.5 to 3.5 feet (ft.), respectively (SRH, Inc., 1988). Polychlorinated biphenyls (PCBs) and solvents were not detected above the instrument detection limits in any of the samples (SAIC, 1991).

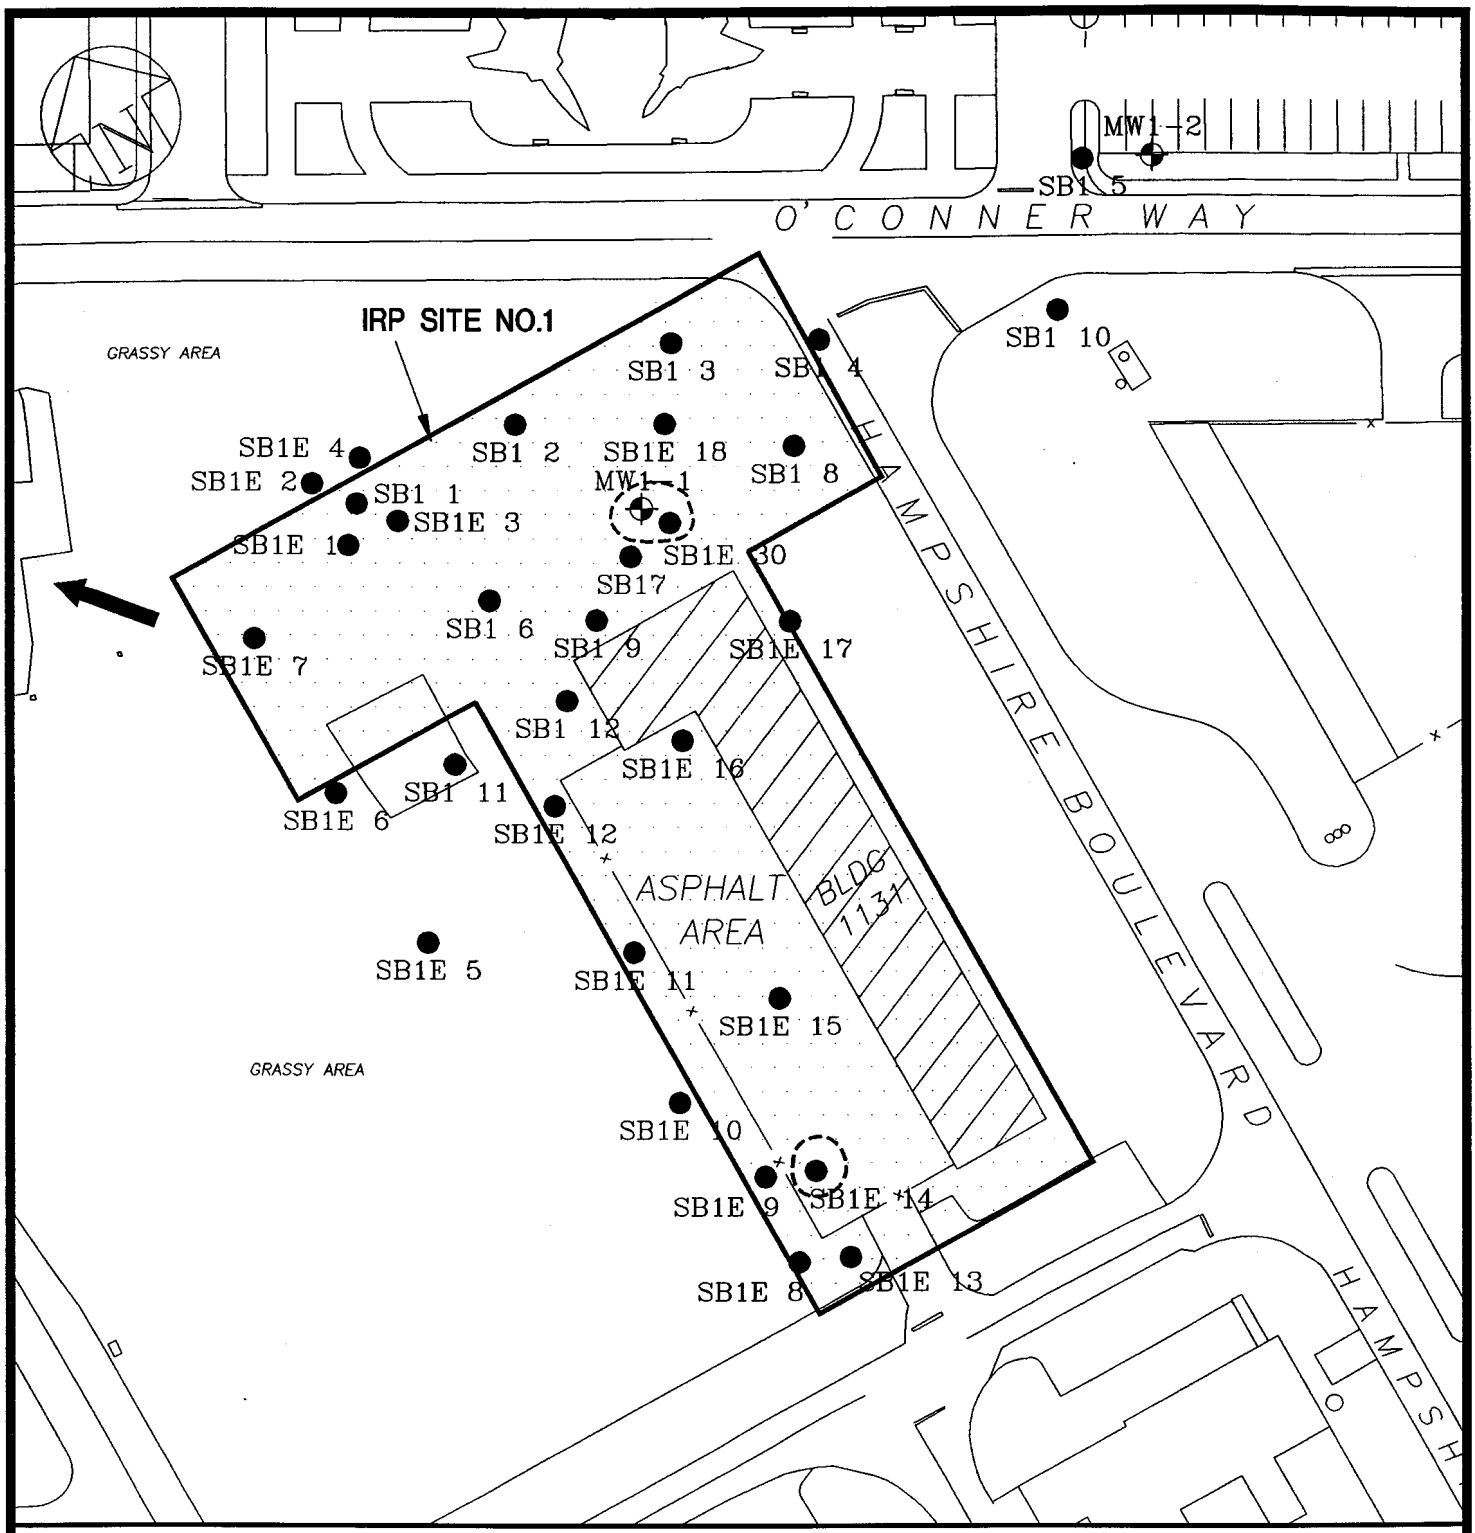

FIGURE 3.1

PL_FIG\ST_1-2

IRP SITE NO.1: EXISTING SAMPLING LOCATIONS

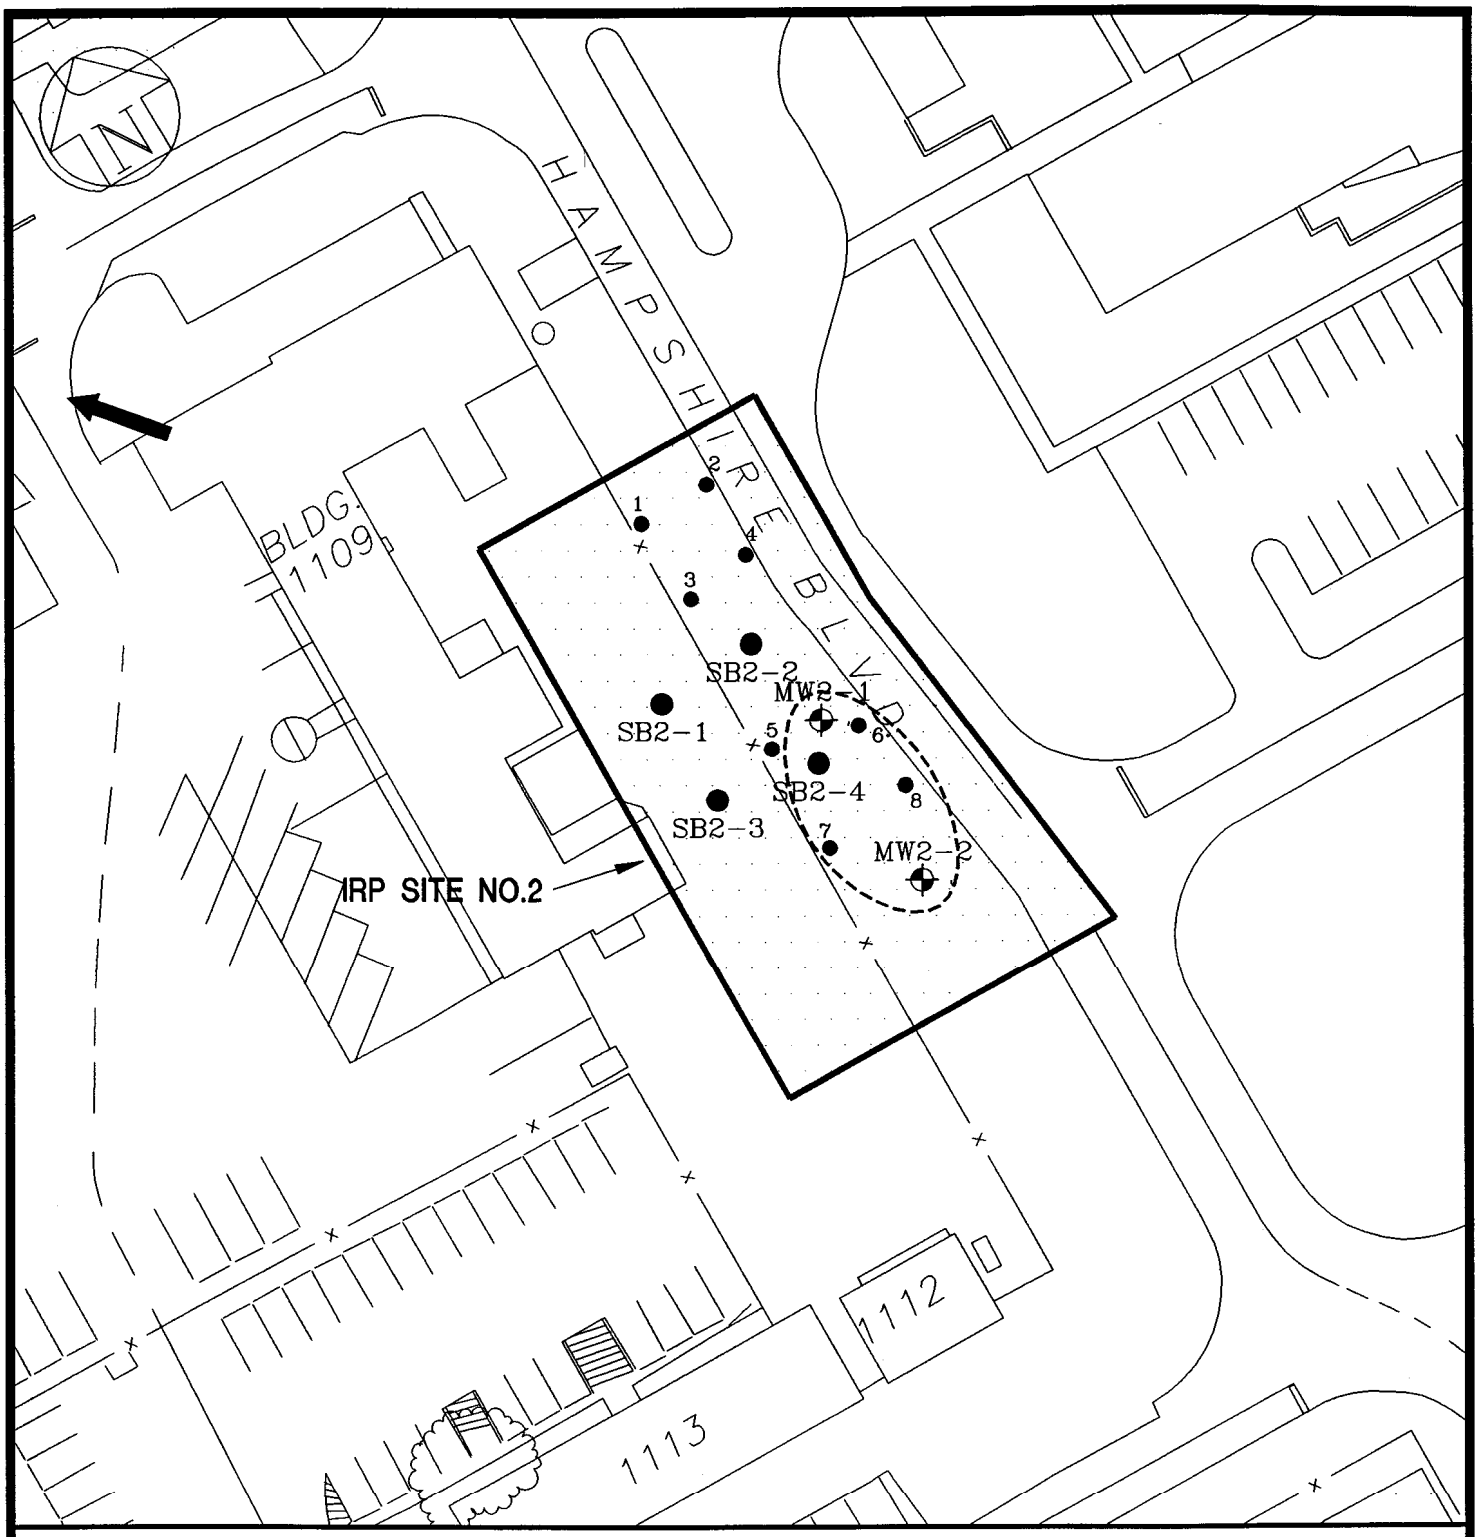
142nd FG, Oregon ANG
Portland International Airport
Portland, Oregon

OPTECH
OPERATIONAL TECHNOLOGIES CORPORATION

DECEMBER 1995

The SI was conducted in two phases at the site: "fast track" and "expanded", in December 1988 and January 1989, respectively (SAIC, 1991). Thirty-five (35) soil borings were drilled from which 27 soil samples were collected from the unsaturated zone during both phases of the investigations (Figure 3.1). Analytical results indicated PCBs in one sample (SB1-1-1) at a concentration of 0.34 mg/kg. Petroleum hydrocarbons (PHCs) were detected in five samples at levels ranging from 10 to 43 mg/kg (samples: SB1-1-1, SB1-5-2, SB1-7-2, SB1-10-1, and SB1-1-22). Volatile organic compounds (VOCs) were detected in two samples collected near monitoring well MW1-1, which contained bromochloromethane, at concentrations of 1,900 and 190 micrograms per kilogram (μg/kg), respectively (SB1E-20 and SB1E-18, headspace analyses using field gas chromatograph).

Methylene chloride and bromochloromethane were detected in saturated soils at IRP Site No.1. Methylene chloride was detected in three samples with concentrations ranging from 35 to 110 μg/kg. Bromochloromethane was detected in eight samples with a maximum concentration of 12,000 μg/kg (SAIC, 1991).



Two monitoring wells, MW1-1 and MW1-2, were installed at the site during the SI field activities (Figure 3.1). Methylene chloride and bromochloromethane were detected in MW1-1, at concentrations of 1,500 micrograms per Liter(μg/L) and 140,000 μg/L, respectively. No VOCs were detected in MW1-2. Metal concentrations were below background levels in both monitoring wells.

The water table at IRP Site No. 1 occurs at a depth of 5 to 7 feet below ground surface (bgs), depending on the seasonal fluctuation rate. The general groundwater flow is to the northwest toward the Columbia River, with a gradient of 0.002 foot/foot (ft/ft) (SAIC, 1991).

Based on the risk assessment results and the low concentration of contaminants in soils, the IRP Site No. 1 soil unit appears to pose no significant threat to human health and the environment, and no further action was recommended for soils. Further investigation of the IRP Site No. 1 groundwater was recommended in the SI Report due to the potential risks and insufficient characterization of the extent of groundwater contamination.

3.2.2 IRP Site No. 2 - Civil Engineering Hazardous Materials Storage Area

The Civil Engineering Hazardous Materials Storage Area (IRP Site No. 2) is located east of Bldg. 1109 (Figure 3.2). IRP Site No. 2 is defined by the former location of the solvent storage shed south of Bldg. 1123. The storage shed and Bldg. 1123 were removed from the area during

DECEMBER 1995

Base construction activities. The PA reported that IRP Site No. 2 was located between the storage shed and Bldg. 1123; however, during the SI site coordination meeting conducted by SAIC (1991), it was determined that the site may have been located beneath the storage shed. The storage shed consisted of an open-walled structure with a gravel floor. Drums of chemicals including solvents and methyl ethyl ketone were stored on wooden pallets at the site.

Bldg. 1123 was a former paint storage building. At present time, the former storage shed area is bisected by a wire mesh fence which runs in a north-south direction.

Underground utilities and storm drains are located on the east and the west sides of the Hampshire Boulevard. Topography of the site is relatively flat.

3.2.2.1 Waste Disposal History and Previous Investigation

Chemical drums, including solvent, thinner, and methyl ethyl ketone were stored in or near the storage shed on wooden pallets at the site. Drum leakage and discolored gravel (oil stain) were reported in the PA as a potential source of contamination (SAIC, 1991).

During test pit excavations at the site (four test pits), eight composite soil samples were collected by SRH Associates in September 1988. Only TPH was detected in two samples; 4 mg/kg and 35 mg/kg at depths of 0.5 and 3.5 ft., respectively. No solvents were detected in the soil samples.

Eight soil samples were collected from four shallow soil borings at the site during the SI field activities (Figure 3.2). Soil samples were collected from depths of 0.5 and 3.5 ft. VOCs were not detected in any of the samples collected from the soil borings. Eight soil gas samples were collected for field screening from the grassy areas east of the site. Soil screening results indicated maximum concentrations (10 μg/L) of trichloroethene in all samples. Tetrachloroethene, chloroform, and 1,1,1-trichloroethane were reported as tentatively identified compounds in the field screening analyses.

Two monitoring wells (MW2-1 and MW2-2) were installed at the site during the SI field activities (Figure 3.2). Groundwater occurs at a depth of 5 to 7 ft bgs. Groundwater flow at the site is to the northwest with an approximate gradient of 0.002 ft/ft.

Trichloroethene and dichloroethene were detected in groundwater samples from both wells: MW2-1 with trichloroethene at 710 μg/L and dichloroethene at 130 μg/L, and MW2-2 with trichloroethene at 430 μg/L and dichloroethene at 28 μg/L (SAIC, 1991).

The SI Report recommended additional characterization of IRP Site No. 2 groundwater because of the high concentrations of trichloroethene in groundwater and the undefined extent of groundwater contamination. Additional soil sampling was also recommended in the SI Report, only to confirm source area(s).

3.2.3 IRP Site No. 3 - Hush House Area

The Hush House Area (IRP Site No. 3) is located at the southeast corner of the intersection of Carey Street and O'Conner Way (Figure 3.3). IRP Site No. 3 was used to test jet engine performance. Waste oil, solvents, and fuel were stored in 55-gallon drums at the southwest corner of the building (HMTC; 1988, SAIC; 1991). An oil/water separator was located approximately 75 ft south of the former Hush House. An exhaust tower and associated piping from the condensation system was connected and drained into the oil/water separator. To make identification of the site areas easier to understand, the former Hush House area investigated during the SI has been designated IRP Site No. 3 Area A, the oil/water separator will be designated Site No. 3 Area B, and an area to the northeast of the Hush House where during construction activities encountered hydrocarbon contamination has been designated as IRP Site No. 3 Area C.

The topographic surface at IRP Site No. 3 is slightly elevated and is approximately 2 to 3 feet above the surrounding land area. The ground surface slopes towards the south and east. Surface water from the site drains into the Main Drainage Ditch (IRP Site No. 4) through a culvert, which passes under Carey Street.

3.2.3.1 Waste Disposal History and Previous Investigation

IRP Site No. 3 was used as a jet engine testing facility. Drums of waste oil, fuel, and solvents were stored at the southwest corner of the building on an unpaved surface. These wastes may have impacted site soils due to spills, runoff, and washoffs at the former Hush House.

OPTECH
OPERATIONAL TECHNOLOGIES CORPORATION

DECEMBER 1995

IRP Site No. 3 Area A, Hush House Area

Two composite soil samples were collected from four test pits by SRH Associates in September 1988, from a depth of 0.5 and 3.5 ft bgs. TPH was detected at a maximum concentration of 17 mg/kg in the deeper sampling interval. Among polycyclic aromatic hydrocarbons (PAHs), only low concentrations of pyrene and fluorene were detected in soil samples (SRH, 1988).

Eight soil samples were collected from depths of 1 and 8 feet during the SI field activities (SAIC, 1991). Samples were collected from the southwest corner of the building (Figure 3.3). Low concentrations of TPH (SB3-1-2, 2.0 mg/kg) and methylene chloride (SB3-2-1R, 0.041 mg/kg; SB3-3-2, 0.026 mg/kg; SB3-4-2, 0.017 mg/kg) were detected in samples collected from the deeper interval. However, the same chemicals were also detected in quality assurance/quality control samples indicating possible cross contamination had or occurred or that the chemical was a laboratory artifact.

No VOCs were detected in the groundwater sample collected from monitoring well MW3-1.

The SI Report recommended no further investigation of IRP Site No. 3, Area A - southwest corner of the former Hush House, because of the absence of significant contamination and the low risk associated with the original area investigated (SAIC, 1991). However, more recent information from Base personnel indicates that soil and groundwater contamination may be present at IRP Site No. 3, Area C - northeast corner of the former Hush House; additional site characterization activities in this area are warranted.

IRP Site No. 3 Area B, Oil/Water Separator

During the excavation and removal of the oil/water separator in August 1993, stained soils were observed in the excavation. There has been no previous investigation in this particular area of the site.

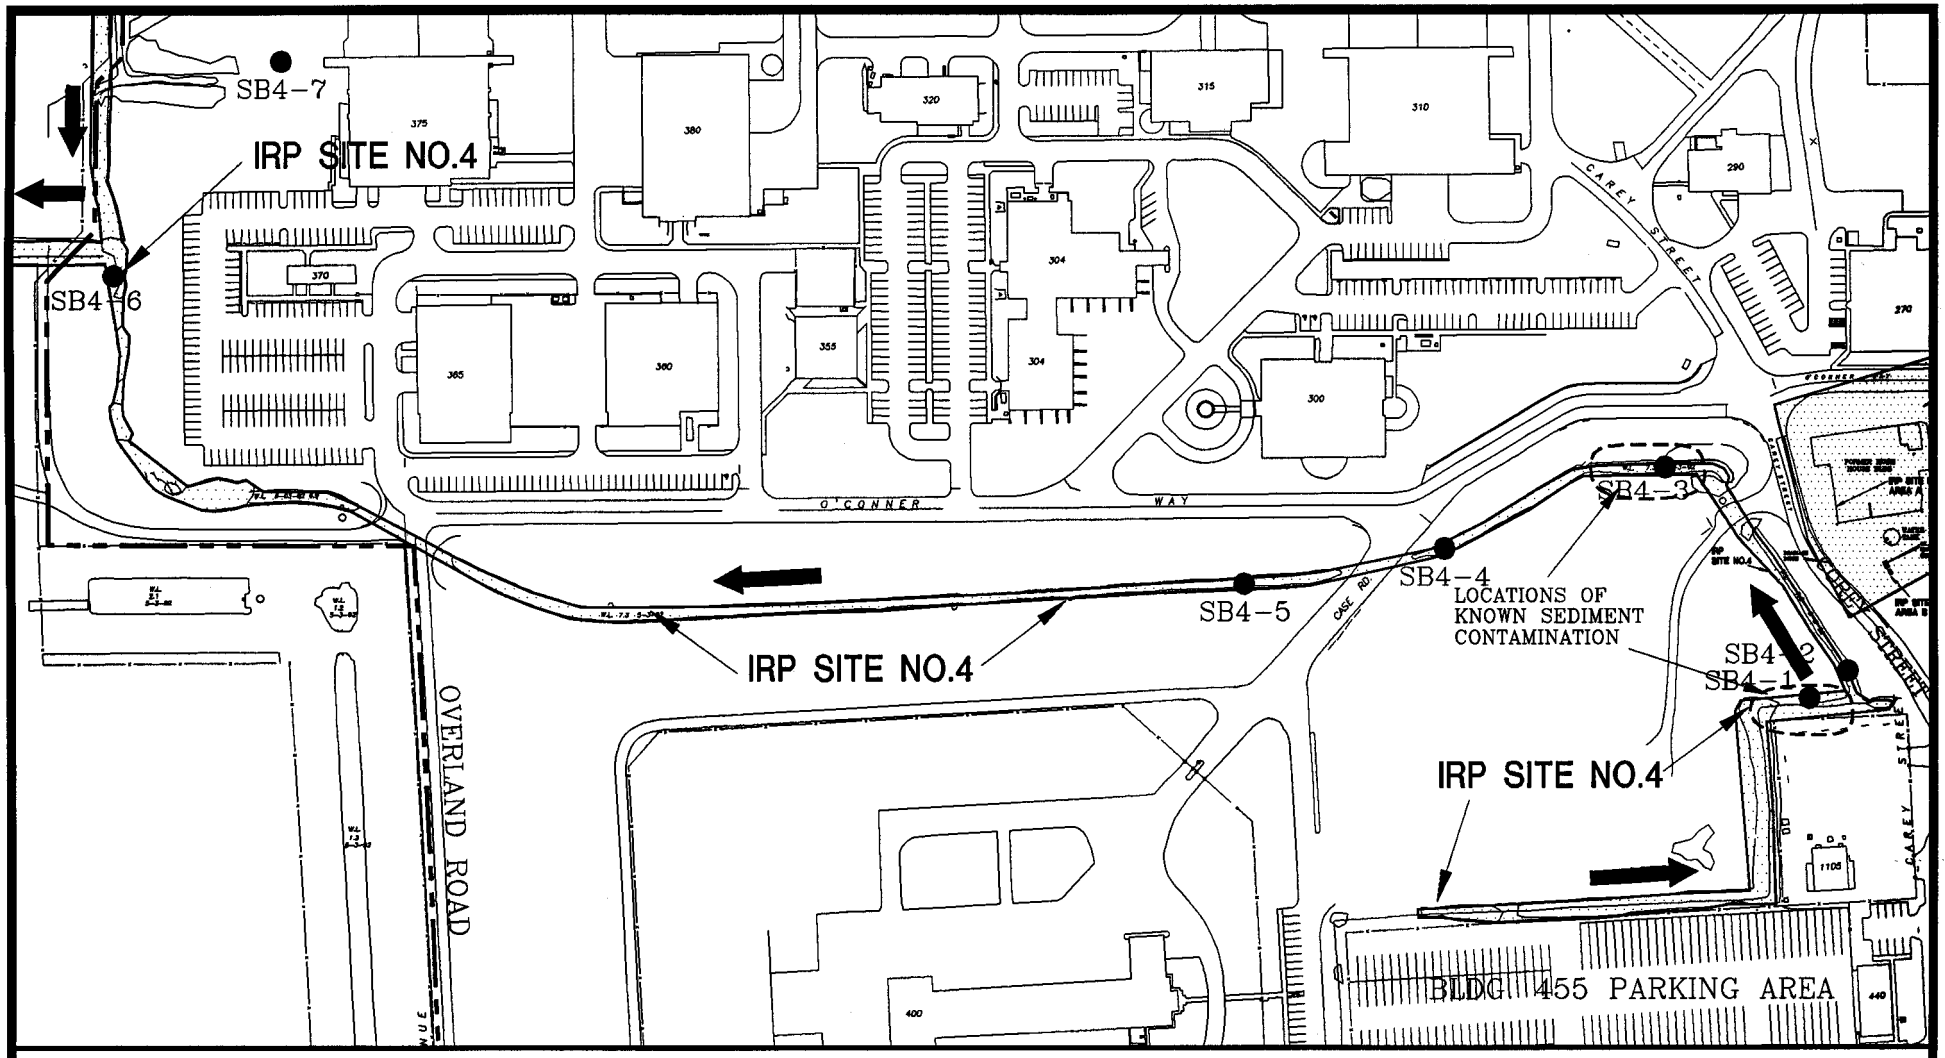
Based on more recent information that soil and groundwater contamination may be present at the former oil/water separator site area, IRP Site No. 3 Area B, additional site characterization activities in this area are warranted.

IRP Site No. 3 Area C, Construction Area

In 1994, the Base reported fuel-related contamination in soils at the northeast corner of the former Hush House concrete pad. Soil contamination discovered during excavation, was noted to occur at depths up to 8 ft bgs and was in contact with the groundwater. No samples were collected and analyzed. No previous investigation in this area of the site has occurred.

3.2.4 IRP Site No. 4 - Main Drainage Ditch

The Main Drainage Ditch (IRP Site No. 4) is located on the west central portion of the Base and receives fluids from drainpipes fed by surface catchment, runway spillage, open ditches, Base surficial overflow, and stormwater and storm sewer piping systems (Figure 3.4). The fluids in the Main Drainage Ditch flow across the western boundary of the Base and empty into the Columbia Slough via a pumping station.



During initial field surveillance activities and sampling, HMTC (1987) reported the presence of fuel and oil in the Main Drainage Ditch downstream from the apron area. Fuel spills from industrial facilities located adjacent to the Main Drainage Ditch have been reported by the Base personnel (SAIC, 1991).

3.2.4.1 Waste Disposal History and Previous Investigation

IRP Site No. 4 receives fluid from stormwater and sanitary sewer lines, surface runoff, and open ditches. Accidental spillage, indirect discharge, and washoff water containing residual chemical constituents from industrial facilities located adjacent to the Main Drainage Ditch may have impacted sediments in the ditch.

Limited sediment and surface water sampling has been conducted in the drainage ditch downstream of the Base (R.N. Smith Associates, 1987). Lead was detected with a concentration ranging from 32 to 2,700 mg/kg. The source of pollutants that entered this portion of the ditch has not been defined (HMTC, 1987).

During the SI field activities, seven sediment samples (SB4-1 through SB4-7) were collected from the Main Drainage Ditch (Figure 3.4) and analyzed for five metals (cadmium, chromium, lead, nickel, and zinc), PHCs, and VOCs. PHCs were detected in all seven samples with concentrations ranging between 0.58 to 10 mg/kg (SB4-6 and SB4-7). No VOCs were detected

in any of the samples, except those that are attributed to the common laboratory chemicals (methylene chloride and acetone). Metals were detected in all samples with the highest concentrations in samples SB4-1 and SB4-3. Samples with the highest metal concentrations are associated with the locations where PHCs were highest (SAIC, 1991). This association may be an indication of the fuel and waste oil spills and releases from the industrial facilities. Surface water samples have not been collected from the Main Drainage Ditch or from the outfalls leading into the ditch.

The preliminary risk assessment for sediment conducted for the site concluded that no adverse carcinogenic or noncarcinogenic effects would be expected under the risk calculation assumptions for human receptors (SAIC, 1991). Metal concentrations in sediment samples collected from the site were also compared with Washington Marine Sediment Quality Standards (WMSQS). Detected metal concentrations were all below WMSQS. Since PHC results are not chemical specific and toxicity information is not available, PHCs were not considered in risk assessment calculation.

The SI recommended further investigation of this site because of the potential presence of contaminants in the surface water and sediments. In addition, the full nature and extent of contamination in the ditch has not been characterized.

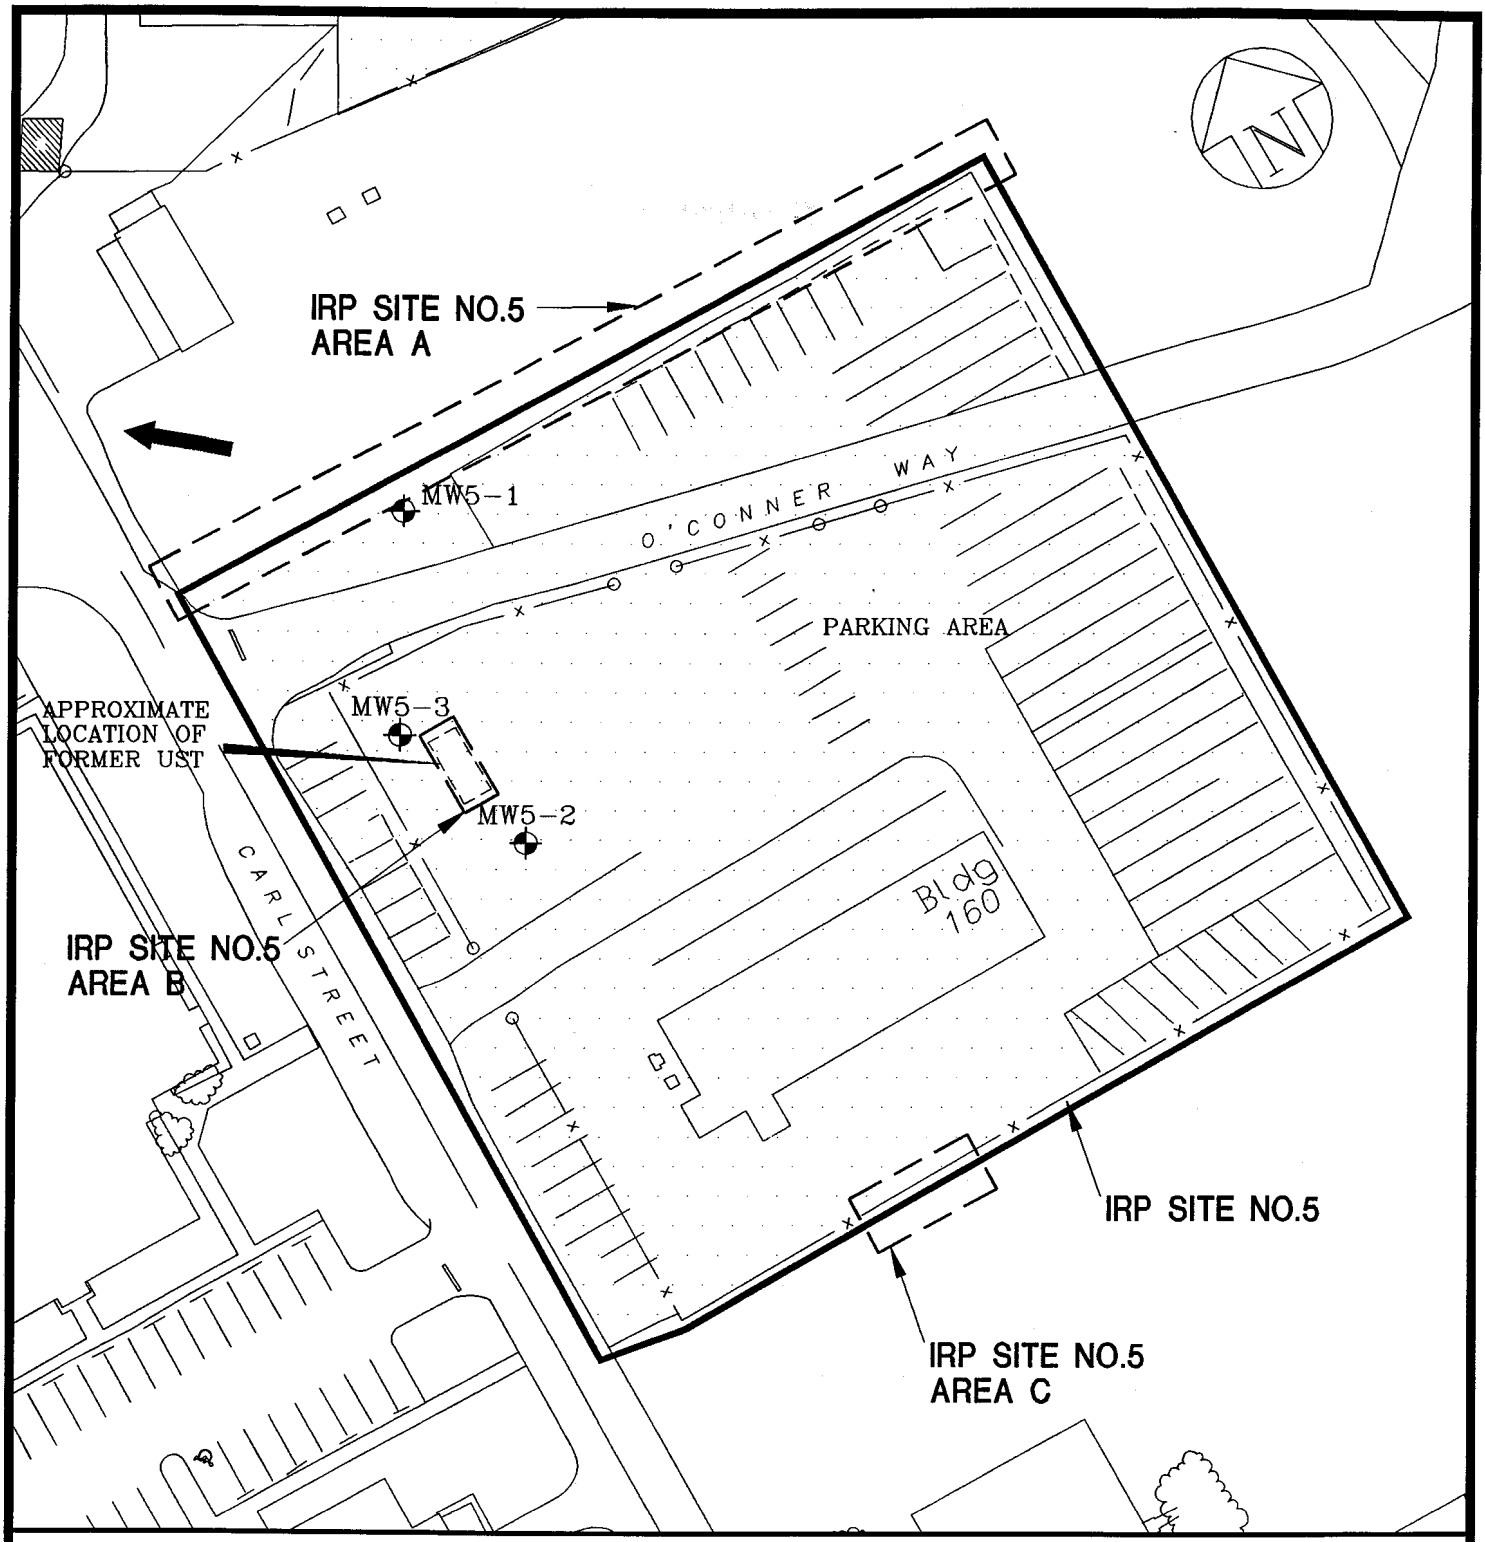
3.2.5 IRP Site No. 5 - Aerospace Ground Equipment (AGE) Maintenance Shop

The AGE Maintenance Shop (IRP Site No. 5) consists of possible waste disposal areas along two fence lines, the first located approximately 200 ft north of Bldg. 160 and the second approximately 50 ft south of Bldg. 160 (Figure 3.5). A former leaking UST, Bldg. 1225, and the northern fence line were removed from the site in November and December, 1988. O'Conner Way bisects the former location of the north fence line.

Topography at the site is relatively flat with a slight slope toward the north and the east. Storm drain inlets are located on the east and south ends of the site. Storm sewer and water lines are located along the east side of Carl Street, and power lines pass north of the former location of Bldg. 1225.

3.2.5.1 Waste Disposal History and Previous Investigation

Wastes generated at the AGE Maintenance Shop include spent battery acid, solvents, lubricants, antifreeze, cleaning solutions, and automobile fluids. These wastes were possibly disposed along the northern and southern fence lines as evidenced by soil staining. The former leaking UST at IRP Site No. 5 contained heating oil. The UST was excavated and removed in late 1988.



During the SI field activities, surficial soil stains were observed along the northern and southern fence lines. Six soil borings were drilled along the northern fence line (Figure 3.5). Soil samples were collected from 1 and 3 feet depths (SB5-1 through SB5-6) and were analyzed for VOCs, semivolatile organic compounds (SVOCs), and six metals (cadmium, chromium, iron, lead, nickel, and zinc).

VOCs and SVOCs were not detected in any of the soil samples collected from along the northern fence line, except common laboratory contaminants (methylene chloride and acetone). Bis(2-ethylhexyl)phthalate was detected in seven soil samples. Cadmium, lead, and zinc were detected in concentrations above the background levels.

One monitoring well (MW5-1) was installed at the site on the northeast corner of Bldg. 1225 during the SI field activities (Figure 3.5). Groundwater at the site occurs at a depth of 5 to 8 feet and flows to the northwest with a gradient of 0.003 ft/ft (SAIC, 1991). Trichloroethene and Bis(2-ethylhexyl) phthalate were detected at a concentration of 6.2 and 98 μg/L, respectively. Sulfate was detected at a concentration of 42 mg/L. MW5-2 and MW5-3 were installed as part of a UST investigation and samples collected and analyzed were non-detect.

Stressed vegetation was observed by Air National Guard personnel along the southern fence line during a site visit in 1993. No previous investigation of the southern fence line area has occurred.

The Preliminary Risk Assessment indicated that no adverse carcinogenic or noncarcinogenic effects would be expected for the contaminants identified in the groundwater, surface and subsurface soils. However, the concentration of trichloroethene detected in groundwater exceeded ARARs. The SI recommended an investigation to address groundwater contamination in the northern fence line area. Based on more recent information, the southern fence line is also recommended to be investigated for possible soil and groundwater contamination.

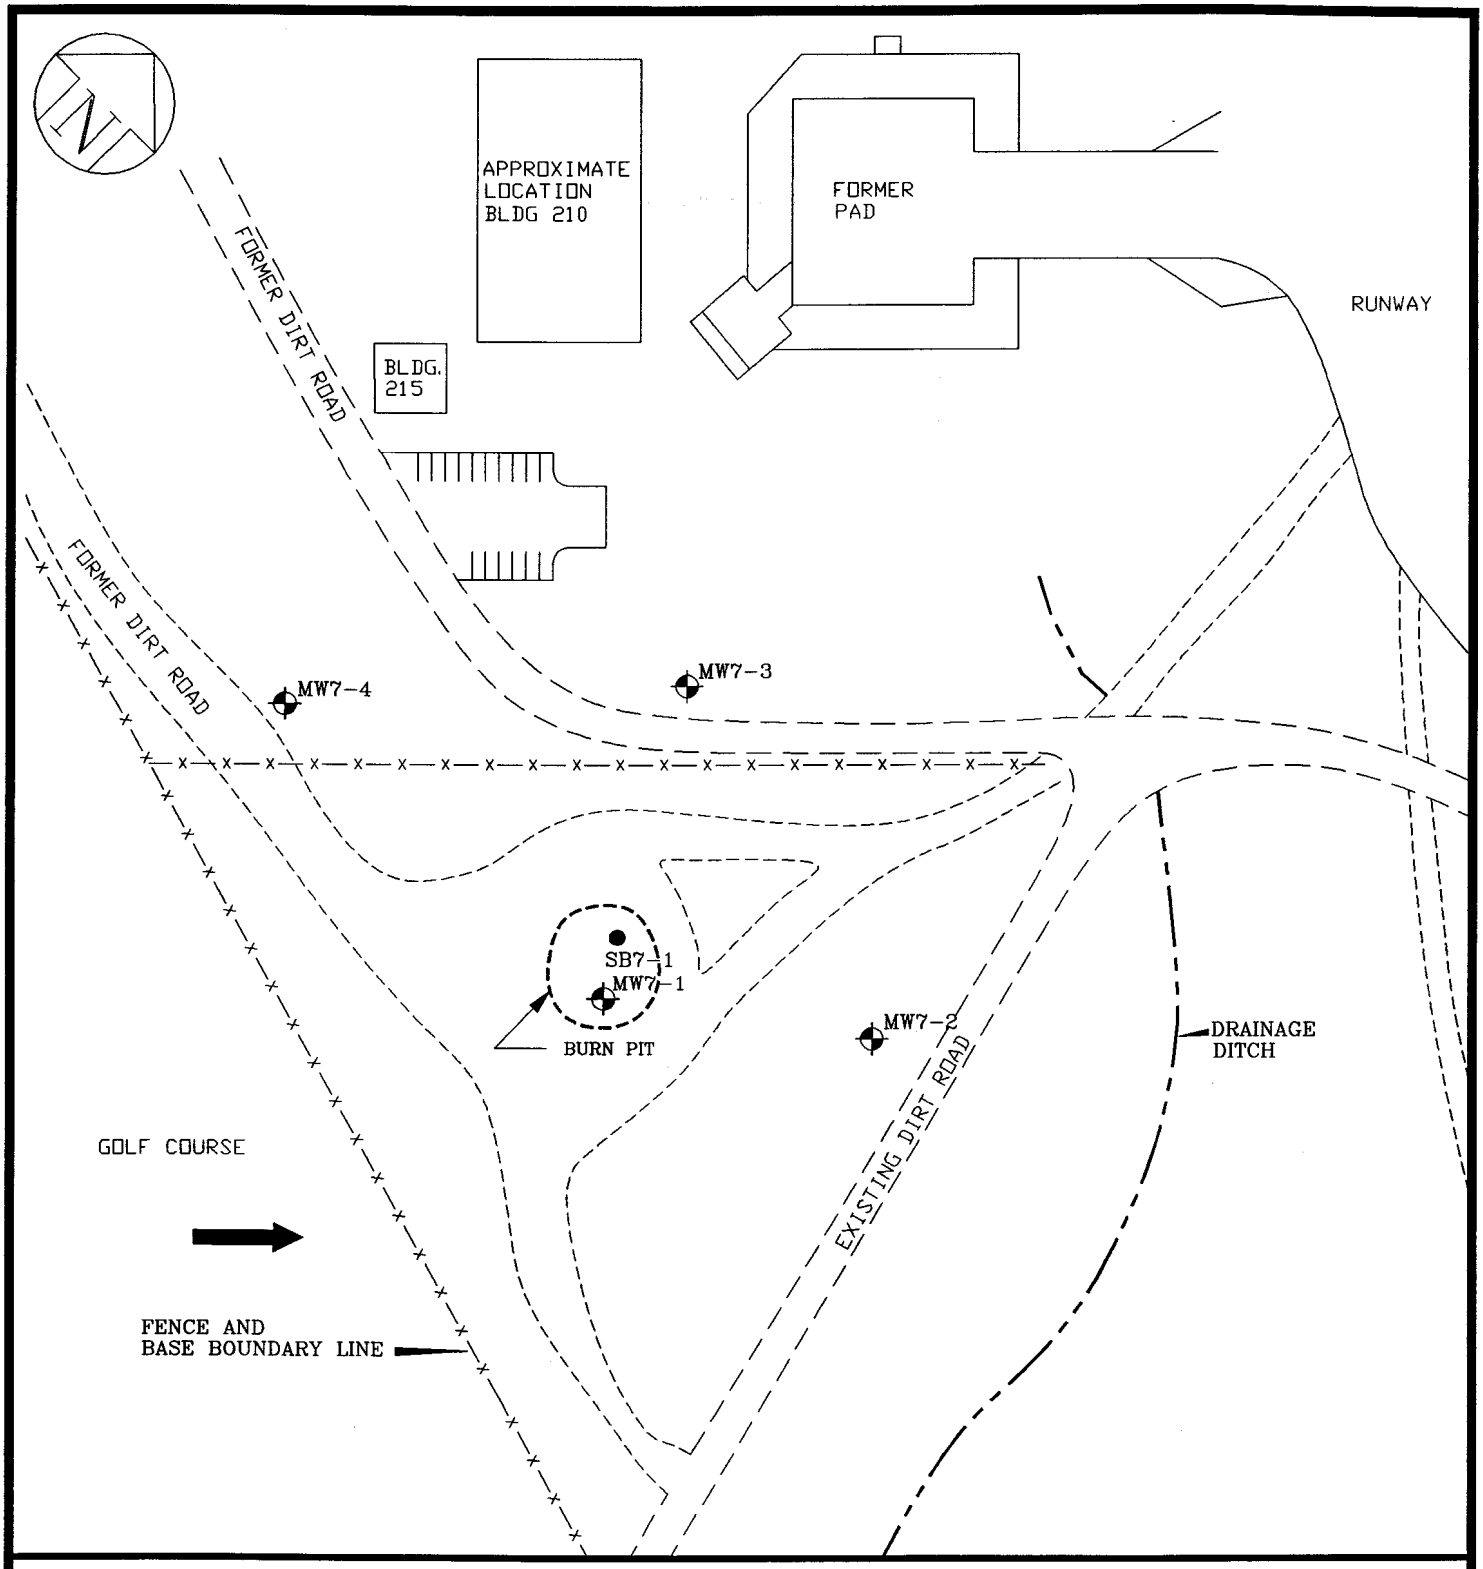
3.2.6 IRP Site No. 7 - Burn Pit Area

The Burn Pit Area (IRP Site No. 7) is located to the southeast side of Bldg. 210, outside of the Base boundary (Figure 3.6). The burn pit was used as a fire training exercise area between 1957 and 1979. Several thousand gallons of waste oil, jet fuel (JP-4), solvent, and flammable liquids were burned each year (SAIC, 1991). The pit area has been filled with gravel and compacted.



Groundwater occurs at a depth of 9 to 15 ft bgs and the flow direction is to the northeast with a gradient of 0.003 ft/ft.

3.2.6.1 Waste Disposal History and Previous Investigation

During the SI field activities, a soil gas survey, and soil and groundwater sampling were conducted at IRP Site No. 7. Samples for soil gas survey were collected based on a 60-foot grid center (Figure 3.7) and analyzed for methylene chloride, bromochloromethane, dichloroethene, trichloroethene, carbon tetrachloride, benzene, toluene, xylenes, and total hydrocarbons. The soil gas survey confirmed that the highest concentrations of contaminants were confined to the burn pit area. Total VOCs were detected at a maximum of 1,100 μg/L (air) as depicted in Figure 3.7. Three soil samples (SB7-1-1, SB7-1-2, and SB7-1-3) were also collected from one soil boring from the center of the pit (Figure 3.6), at a depth of 1, 5, and 10 feet, and analyzed for TPH and lead. Lead was detected at a concentration ranging between 2.6 and 5.6 mg/kg, and TPH concentrations ranged between 11 to 72 mg/kg.

Four monitoring wells were installed during the SI field activities. Groundwater was encountered at approximately 9-15 ft during the SI. Groundwater samples were analyzed for VOCs, SVOCs, lead, and field parameters (pH, temperature, and specific conductance). Lead was detected at a concentration ranging between 1.6 and 14 μg/L. VOCs and SVOCs were not detected in any of the groundwater samples, except the common laboratory contaminant methylene chloride.

Preliminary risk assessment conducted at the site did not indicate any adverse carcinogenic or noncarcinogenic effects for surface and subsurface soils and the groundwater (SAIC, 1991). However, the SI Report recommended further investigation of the site because of the widespread presence of chlorinated hydrocarbons (soil gas survey) and the need to characterize more completely the extent and nature of site contamination in soils and groundwater.

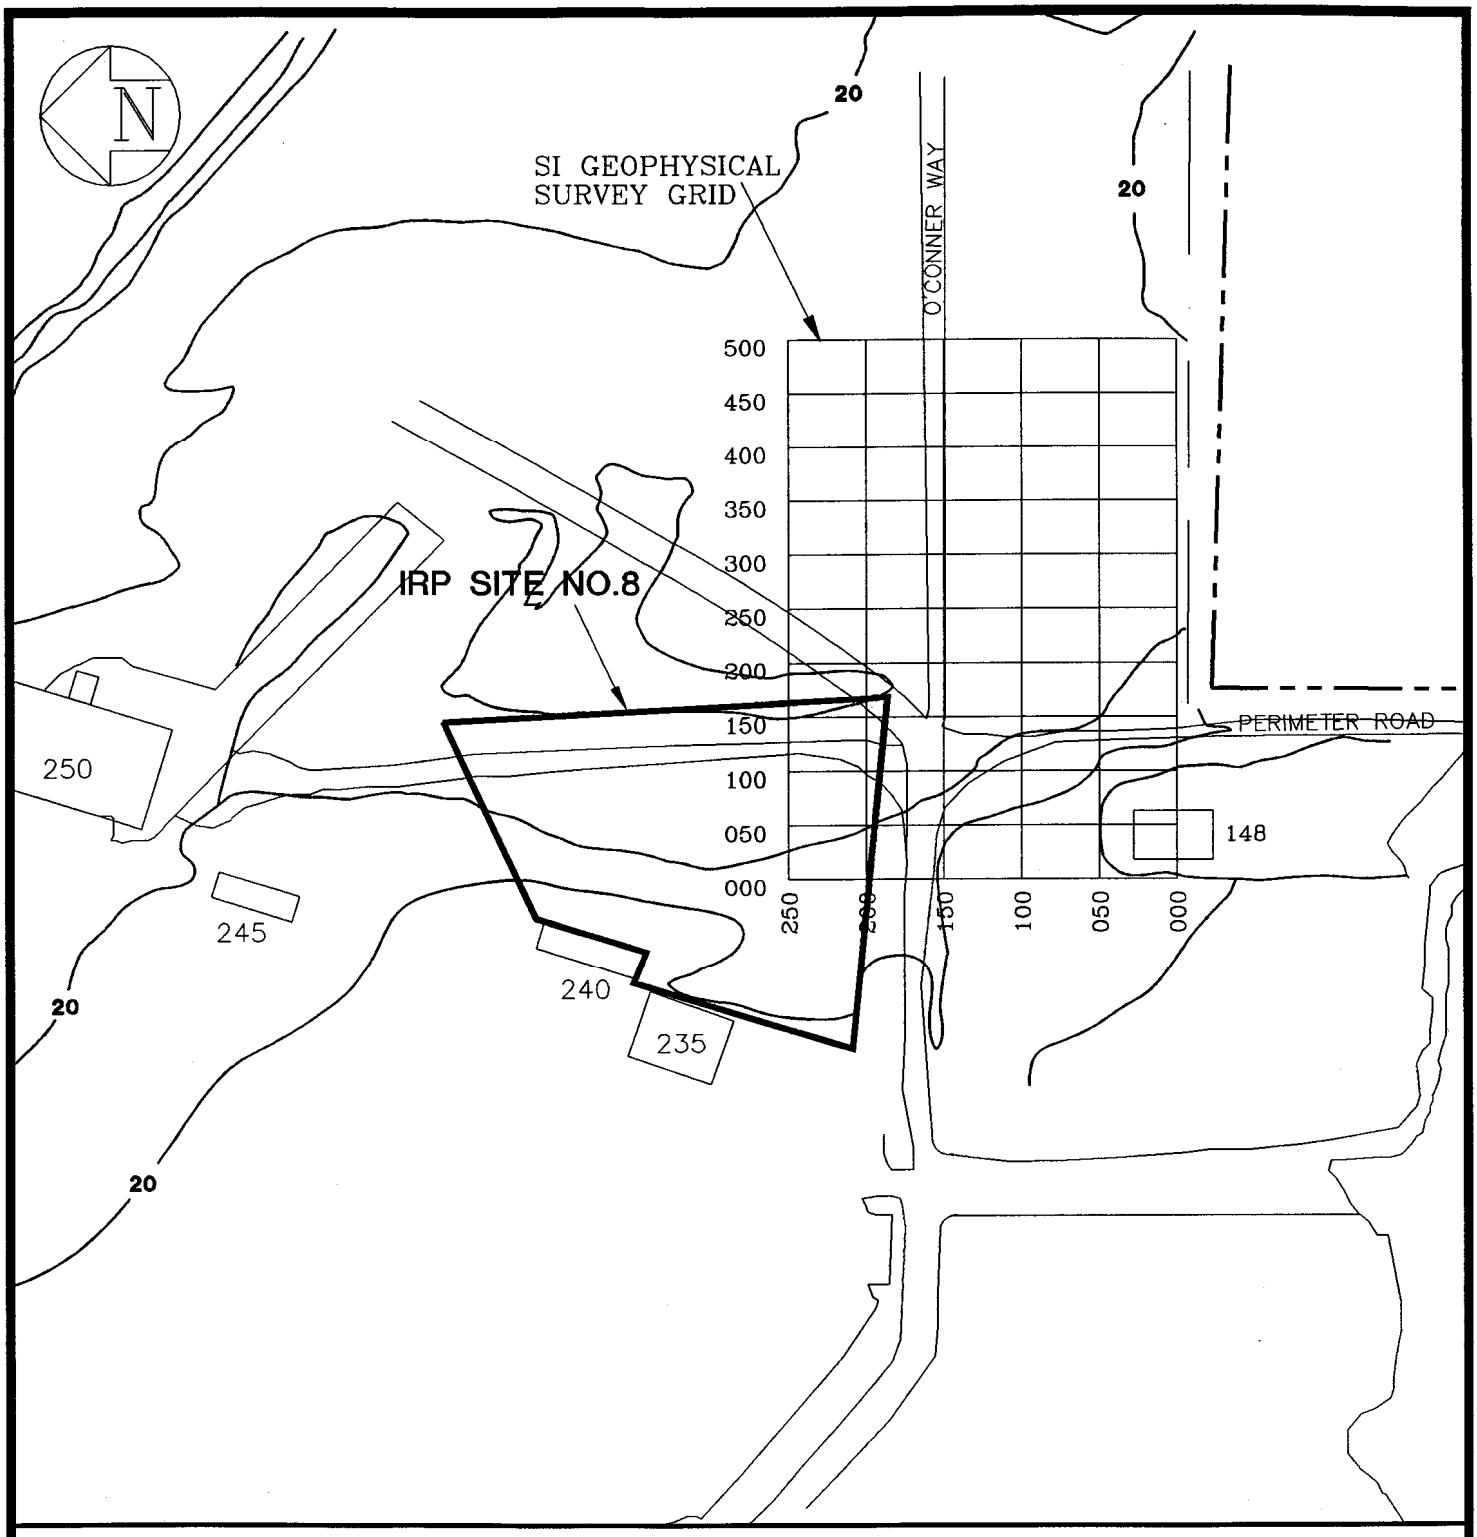
3.2.7 IRP Site No. 8 - Sanitary Landfill (SLF)

The Sanitary Landfill (IRP Site No. 8) is located east-southeast of Bldgs. 250, 245, 235, and 255 (Figure 3.8). A very limited amount of information is available to identify the exact location and disposal activities at the SLF (HMTC, 1987). IRP Site No. 8 was active between 1949 and 1956 and occupied an area of approximately one acre (SAIC, 1991). Landfilling was done by excavating trenches 6 to 8 ft deep, 60 to 70 ft long, 10 ft wide, and 5 to 20 ft apart. Trenches were then covered with 3 to 4 ft of excavated materials.

3.2.7.1 Waste Disposal History and Previous Investigation



The SLF received wastes generated by the Base and the Army National Guard between 1949 and 1956. The waste consisted of ordinary shop and building refuse, paint cans, oil and paint residue, batteries, waste papers, and broken equipment and parts.

In order to determine the location of trenches associated with the landfill activities at the site, historic aerial photographs found at the U. S. Army Corps of Engineers and Base files were reviewed during the SI (SAIC, 1991). Review of the aerial photographs did not reveal significant information to delineate boundaries of buried trenches at the site. However, evidence of surface disturbances were identified on the aerial photographs.

Subsequent to aerial photograph review, geophysical surveys were conducted at the site (Figure 3.8). An electromagnetic survey (EMS) and Total Field Magnetic (TFM) survey were conducted to locate landfill trenches. The survey grid was established based on a 50 ft grid center (maximum surveyed area of 250 ft by 250 ft). Anomalies were detected by both EMS and TFM surveys on the west side of the grid at the site. The source of the anomalies is unknown.

Three trenches were excavated by the Base for underground utility lines in a north-south direction, in the area of anomalies detected by the EMS and TFM surveys and east of Bldg. 250. Landfill material was not encountered in any of the trenches.

No soil or groundwater samples were collected during the SI (SAIC, 1991). However, Base personnel collected soil samples at the site during trench excavation, but that information was not available for evaluation.

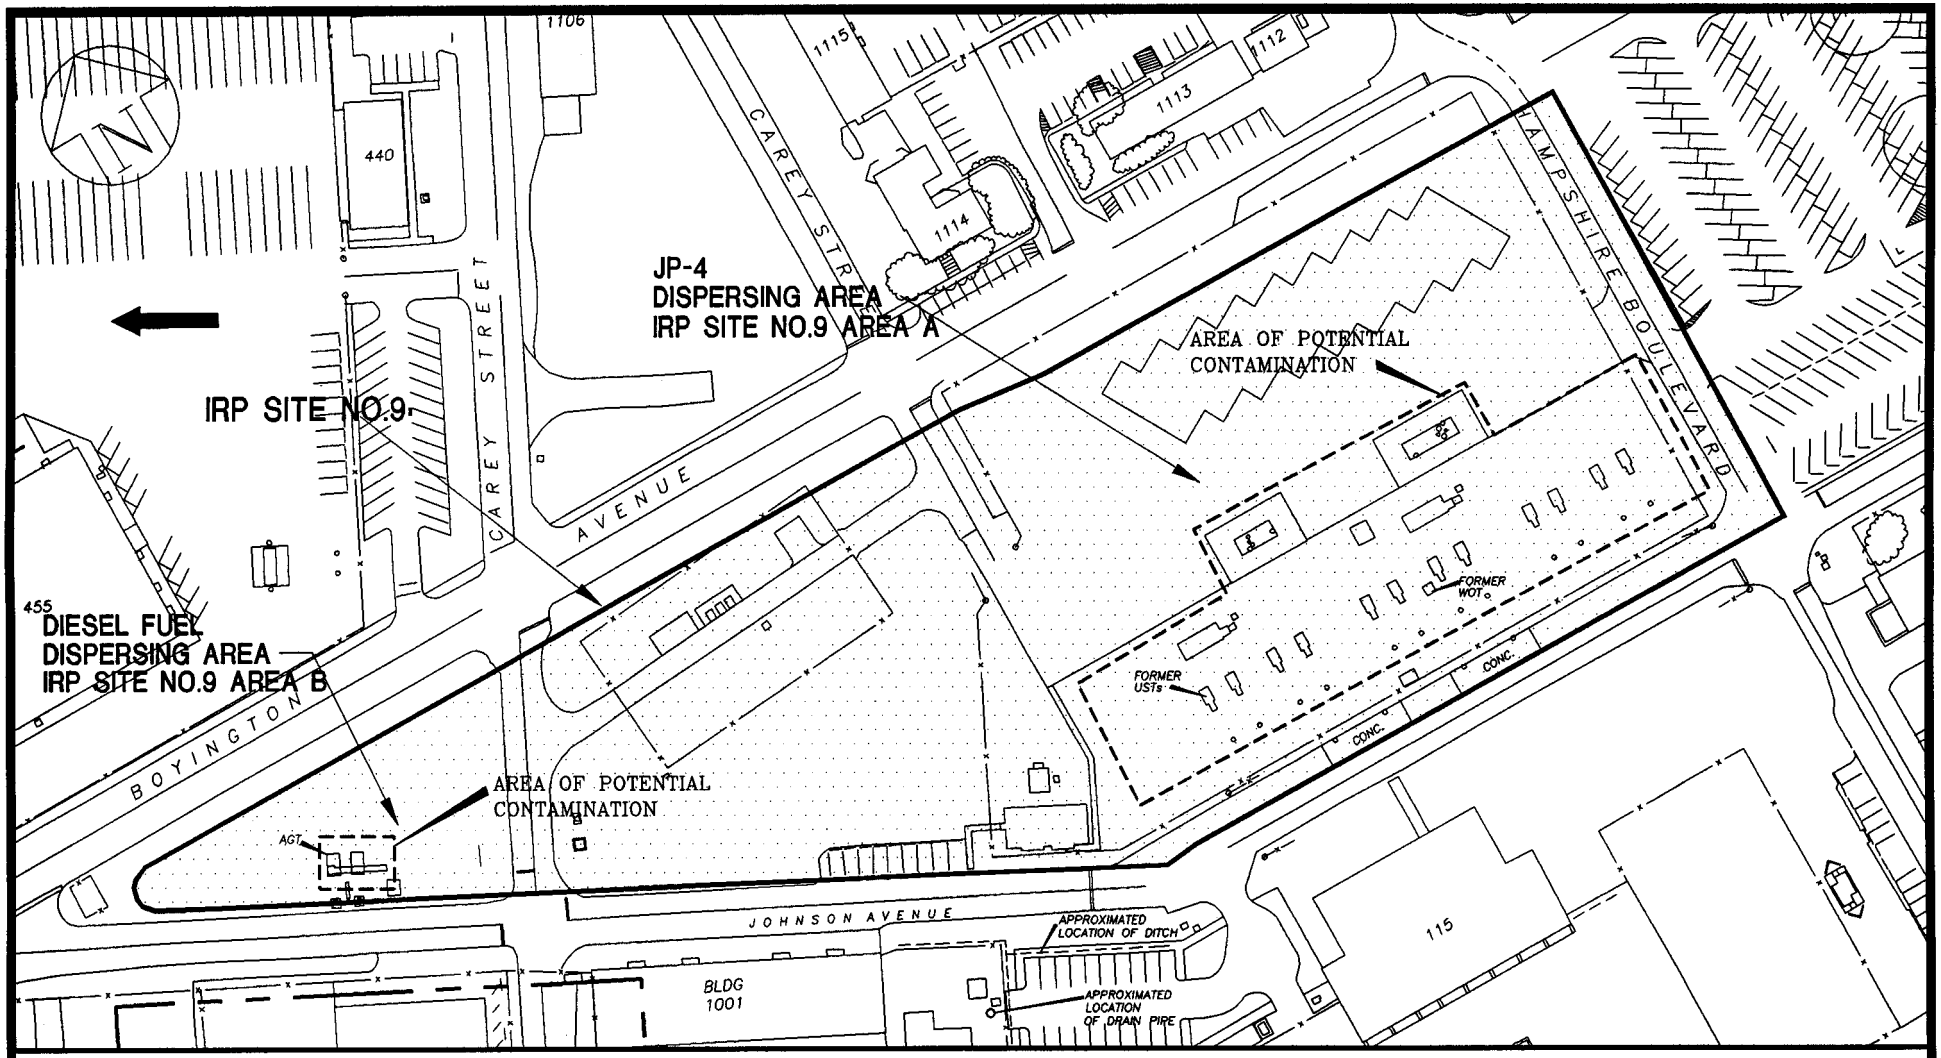
DECEMBER 1995

The SI Report recommended further investigation of the site area to determine the existence and location of the SLF.

3.2.8 IRP Site No. 9 - Petroleum, Oil, and Lubricants (POL) Facility



The POL Facility (IRP Site No. 9) is located at the intersection of Boyington Avenue, Hampshire Boulevard, and Johnson Avenue. IRP Site No. 9 Area A consists of two separate source areas. IRP Site No. 9 Area A is the former POL facility that included two fuel dispensing areas, and IRP Site No. 9 Area B is the former diesel dispensing area (Figure 3.9). IRP Site No. 9 Area A contained twelve 25,000-gal USTs and a waste oil underground storage tank. The thirteen USTs were removed in March 1994. IRP Site No. 9 Area B had two aboveground storage tanks (HMTC, 1987) (Figure 3.9).

3.2.8.1 Waste Disposal History and Previous Investigation

The USTs at IRP Site No. 9 Area A had been used in the past to store JP-4 fuel only. Inventories and tank and associated piping tightness test results did not indicate leaks in any of the tanks or supply pipes. The aboveground tanks at IRP Site No. 9 Area B were filled from Johnson Avenue on the southern side of the site.

In 1991, the Base discovered soil contamination and free product at IRP Site No. 9 Area A while performing site construction. Soil contamination was reported to occur from a depth of 2 ft bgs to the water table at the filling stands. Soil samples were collected using a direct push sampling device from a depth of 13 ft bgs, which is the depth of the base of the USTs and approximately 7 ft below the water table. The analytical results indicated there was no soil contamination. Then, in 1994 when the Base decommissioned the USTs, soil samples were collected from the excavation sidewalls and from the standing water within the open excavations. Benzene, toluene, ethylbenzene, and xylenes, TPH (diesel and gasoline fractions), and PAHs were detected in all soil samples (except in areas associated with tank pits 1/2 and 11/12) and all water samples.

No other investigations of IRP Site No. 9 Area A and IRP Site No. 9 Area B have occurred. Based on this information, further investigation of IRP Site No. 9 Areas A and B is warranted.

3.2.9 IRP Site No. 10 - Equipment Washrack

The Equipment Washrack (IRP Site No. 10) is located at the southeast corner of Bldg. 1001 (Figure 3.10). IRP Site No. 10 consists of a concrete pad approximately 30 ft by 30 ft and a drain pipe; it was in operation from 1950 to 1993. The concrete pad (Figure 3.10) slopes toward the east where fluids flow into a roadside ditch located northeast of the drain pipe.

3.2.9.1 Waste Disposal History and Previous Investigation

Limited soil sampling has been conducted at the site by the Base. Two soil samples were collected near the washrack outfall by the Base, from depths of 1 and 3 ft bgs, and analyzed for oil and grease and metals (only the 3 ft sample). Oil and grease was detected in both samples at concentrations of 7,400 milligrams/kilogram (mg/kg) (1 ft) and 760 mg/kg (3 ft), respectively. Barium (110 mg/kg), cadmium (21 mg/kg), chromium (41 mg/kg), and lead (400 mg/kg) were detected in the sample collected from the 3 ft interval.

No other investigation of this site area has occurred. Based on this information, further investigation of IRP Site No. 10 is warranted.

3.2.10 IRP Site No. 11 - Washrack West of Bldg. 250

The Washrack West of Bldg. 250 (IRP Site No. 11) is located at the southeast corner of Apron A and southwest of Bldg. 250 (Figure 3.11). The washrack is used to wash mission aircraft in such a manner that solvent and degreaser are applied before the soap and water mixture. IRP Site No. 11 consists of a concrete pad, 80 ft by 80 ft square, a drain pipe, and an oil/water separator (Figure 3.11). The concrete pad slopes towards the east where fluid is drained into the oil/water separator via the drain pipe. Fluid from the oil/water separator was discharged into the storm sewer prior to 1984 and into the sanitary sewer line after 1984.

The oil/water separator was a concrete lined, three staged, gravity baffled system. The oil/water separator was removed from service after the discovery of cracks in the center stage in 1989.

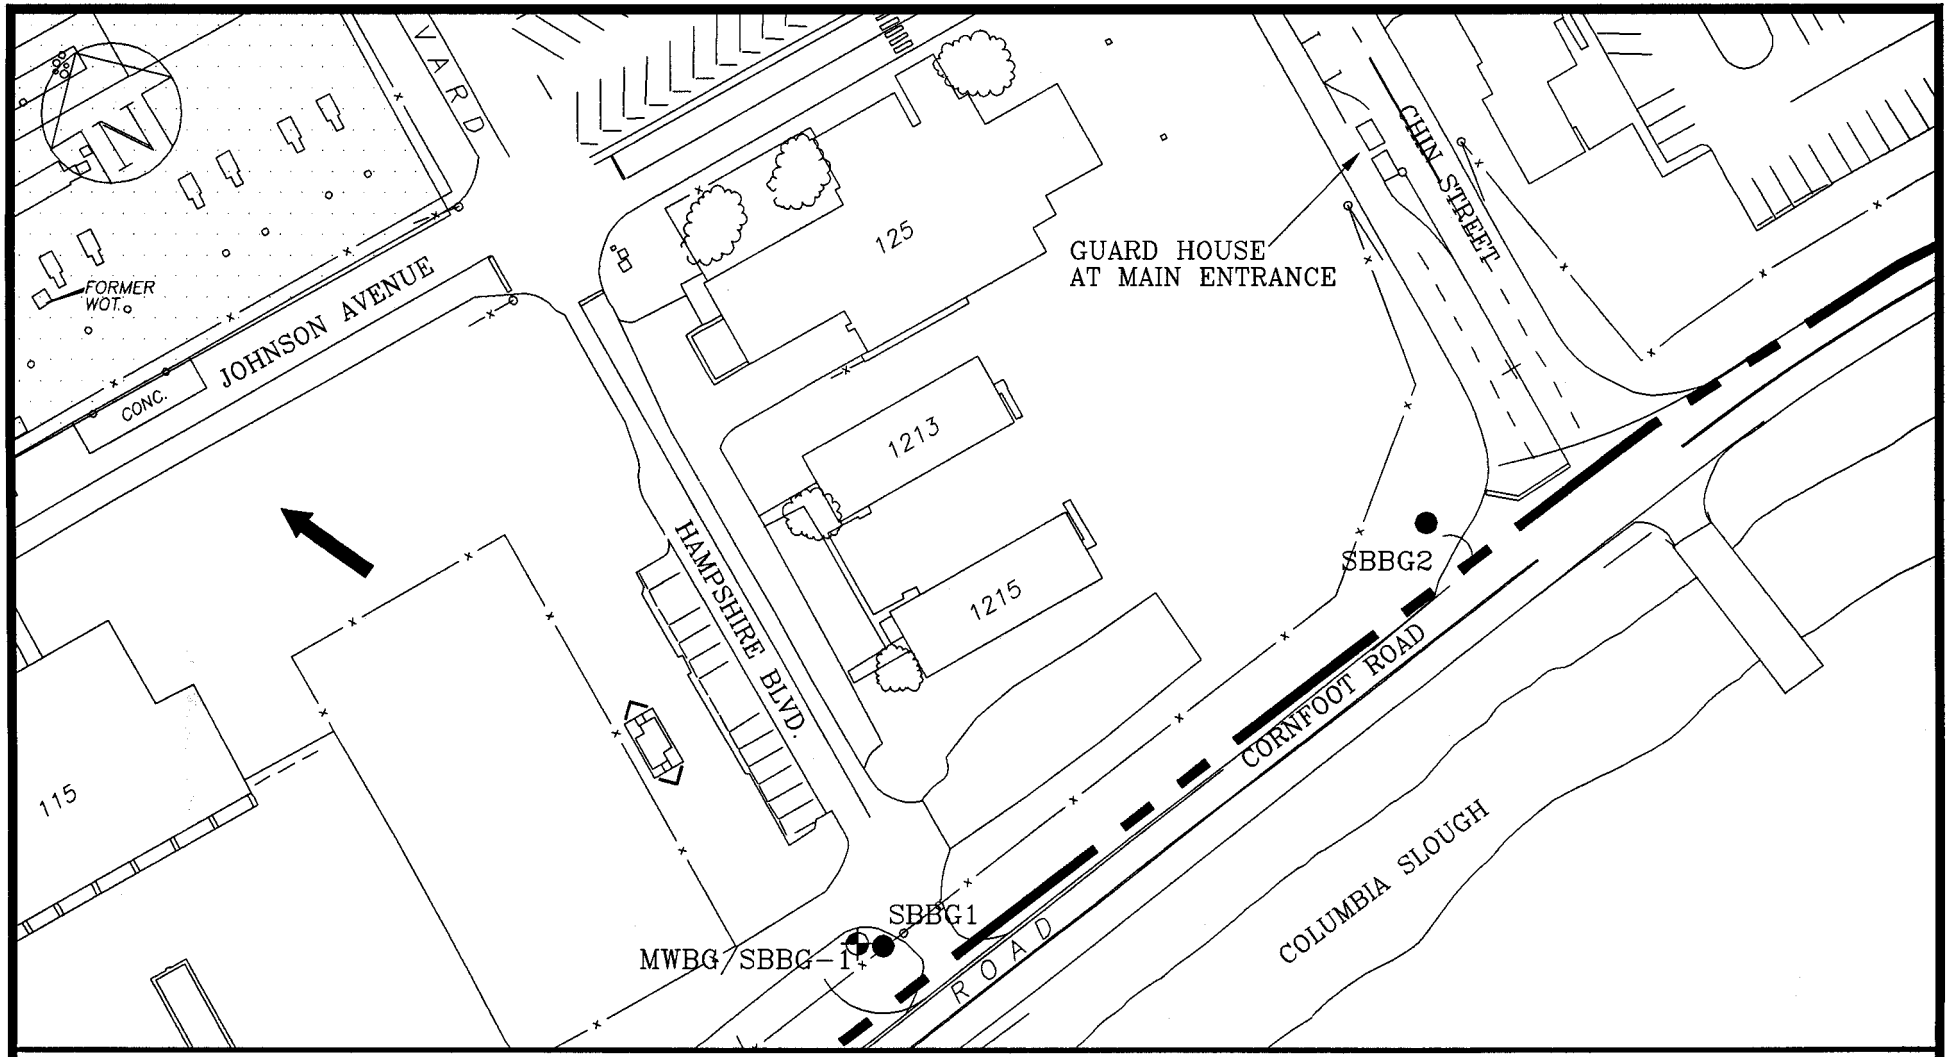
3.2.10.1 Waste Disposal History and Previous Investigation

No groundwater sample was collected from the site. However, during trenching and excavation for utility line installation, soil contamination was observed by the Base personnel on the west side of the concrete pad and the oil/water separator.

One soil sample was collected from the trench excavation at a depth of 3 ft by the Base personnel. TPH was detected at a concentration of 6,000 mg/kg. Metals were also detected in low concentrations in the soil sample (TCLP method).

No other investigation of this site area has taken place. Based on this information, further investigation of IRP Site No. 11 is warranted.



3.2.11 Base Background Conditions and Previous Investigation

During the SI field activities in December 1988 (SAIC, 1991), two soil samples were collected from each of the two background soil borings; SBBG-1 and SBBG-2 (Figure 3.12), at a depth 1 and 8 ft bgs and were analyzed for VOCs, PCBs, and PHCs. Two additional soil samples were also collected in August 1989 from a shallow soil boring (3 ft bgs) and analyzed for SVOCs and selected metals (cadmium, chromium, iron, lead, nickel, zinc, and sulfate).

One groundwater sample was collected from MWBG-1 and analyzed for VOCs, SVOCs, PCBs, PHCs, selected metals (cadmium, chromium, iron, lead, nickel, zinc, and sulfate), and field parameters (pH, temperature, and conductivity).

VOCs, SVOCs, PCBs, and PHCs were not detected in any of the soil or the groundwater samples. Metals were detected in the soil sample at concentrations of 0.20 mg/kg of cadmium, 24 mg/kg of chromium, 25,000 mg/kg of iron, 14 mg/kg of lead, 17 mg/kg of nickel, and 54 mg/kg of zinc.

Metals in the groundwater sample were detected at concentrations of 0.86 μg/L of cadmium, 830 μg/L of iron, 2.2 μg/L of lead, and 30 μg/L of zinc. Sulfate was detected at 13,000 μg/L.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 4.0 ENVIRONMENTAL SETTING

4.1 METEOROLOGY

Meteorological data presented in the PA and SI were derived from local climatological data for the Portland area compiled by the National Oceanic and Atmospheric Administration (NOAA, 1982). The Portland area has a moderate temperature climate characterized by mild rainy winters and warm to hot, dry summers. Approximately 88 percent of the annual total rainfall normally occurs between October and May. The mean annual temperature is about 53° Fahrenheit (F), with winters averaging 40°-50° F and summers averaging 60°-70° F (SAIC, 1991). Annual net precipitation is calculated to be 13.81 inches per year (HMTC, 1987).

4.2 GEOLOGY

The Oregon ANG is situated on the Columbia River floodplain, which is composed of fluvial and lacustrine sediments. The area is relatively flat and is approximately 20 feet above the sea level. The Base occupies part of the Portland Basin, a northwest-southeast trending structural depression which was formed in the early Tertiary and filled with approximately 1,800 feet of sedimentary strata of late Tertiary and Quaternery sediments.

The northern Portland area is underlain by Tertiary and Quaternary sedimentary and volcanic deposits. Eocene and Miocene rocks, the Sandy River Mudstone, Troutdale Formation, Columbia River Sand, Boring Lava intrusions, and Pleistocene-Recent Alluvium are present in the area occupied by the Oregon ANG.

The oldest rock unit in the Portland Basin is Waverly Heights basalt which has a total thickness up to 600 feet (Swanson et al., 1993). The Goble Volcanic Formation is overlying the Waverly. Pittsburgh Bluff and the Scappoose Formation are of marine origin and overlying the Goble. The Columbia River Basalt Group extends over the northern one-third of Oregon and the southeastern Washington area.

The Sandy River Mudstone is the oldest sedimentary unit of the Portland Basin and consists of silt and fine to medium grained sand with some gravel lenses. Plant fossils and wood fragments are present in the silty layers. Clay rich and ash units are predominant in the upper portion of the formation and are interbedded with Troutdale Formation.

The Troutdale Formation interfingers with the Sandy River Mudstone and consists of fluvial conglomerates of quartzite and granite and vitric-lithic sand and conglomerates. To the east of the Base, the unit becomes predominantly sand and gravel, and on the west it pinches out and is replaced by Sandy River Formation (Swanson et al., 1993).

Approximately 200 to 300 feet of sand and gravel of the Columbia River Sand was deposited in the Portland Basin area. The unit is predominantly sand with a small amount of silt and gravel (Hartford and McFarland, 1989). The Boring Lava is of Pliocene/Pleistocene age and consists predominantly of basalt and basaltic andesite.

The Pleistocene Recent Alluvium sediments in Portland Basin include Portland Hills Silt, volcanoclastic conglomerates, terrace deposits, catastrophic flood deposits, and recent river alluvium. Also, mudflow and pyroclastic materials of Mt. St. Helens eruption are present in the Portland Basin. The Portland Silt is a brown, micaceous, clayey, aeolian silt. Volcanoclastic conglomerates overlie the Boring Lava and consist of tuff and breccia interbedded with conglomerates and sandstone (Trimble, 1963). Terrace deposits are present in the Portland Basin area and consist of volcanic gravel, felsic sandstone, and volcanic debris flow.

The catastrophic flood deposits are present in the area and consist of sand, gravel, cobble, and boulder in a micaceous silty and clayey matrix. The recent alluvium deposit of the Columbia River in made up of interbedded silt and sand. Details are provided in the SI report (SAIC, 1991).

4.3 SOILS

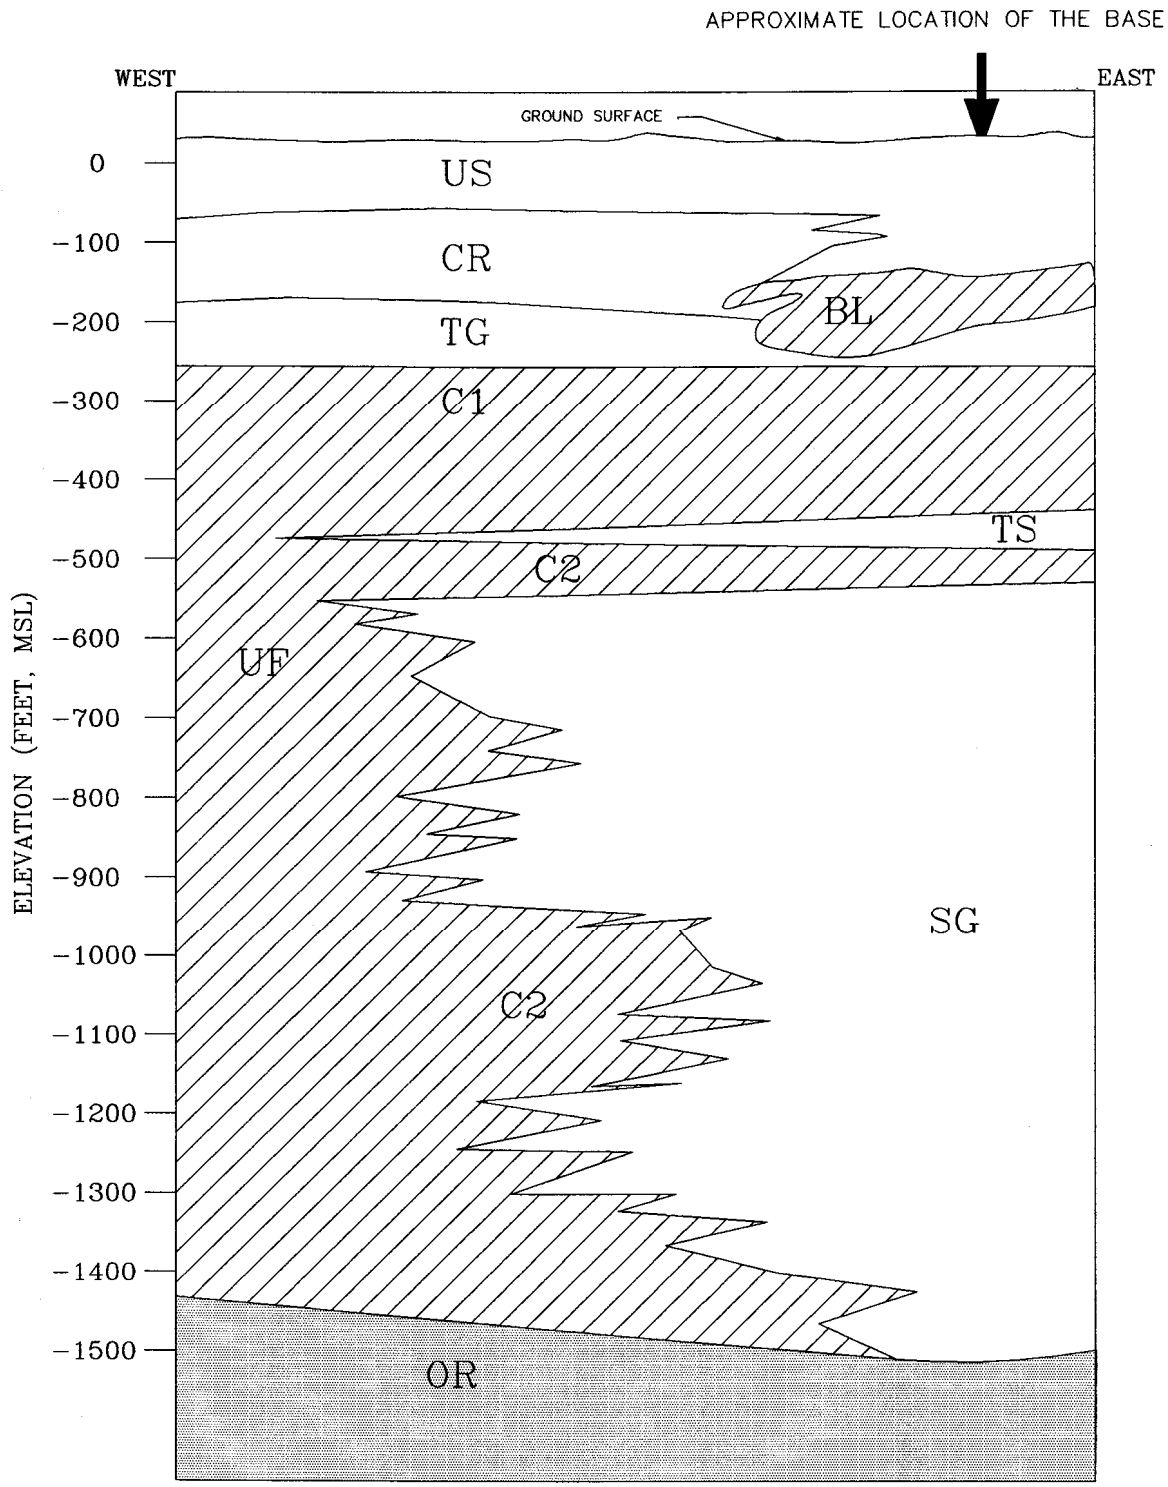
Pilchuck soils, a dark grayish brown to dark brown soil with high permeability, underlies most of the Base. The Sauvie-Rafton soils, a poorly drained, silty, loam soil, occupies the southeastern corner of the Base. The surficial soil is approximately 15 inches thick and is underlain by a dark brown, silty loam to a depth of 60 inches. Most of the areas on the base have been elevated with dredged river sediment and floodplain soils with a high silt and cobble content.

4.4 SURFACE WATER

The Base is located between two main surface bodies: Columbia River on the north and the Columbia Slough (Upper and Lower) on the south. Willamette River is located approximately 4-½ miles southwest of the Base. Surface runoff from the Base is directed toward the Upper

Columbia Slough (Figure 1.1) via the Base Main Drainage Ditch (IRP Site No. 4). According to the Bureau of Environmental Services Report (1988), the Upper Columbia Slough is physically isolated from the lower slough and the Columbia River by the weir. Water can be pumped over the weir from the upper slough to the lower slough. The 100-year flood plain elevation for the area surrounding the Base is 14 feet mean sea level (MSL), and the average water level in the upper slough is 8 feet MSL. The Base elevation varies from 13 to 20 feet MSL (SAIC, 1991).

4.5 GROUNDWATER



There are six hydrostratigraphic units in the Portland Basin area (Swanson et al., 1993). These units are as follows:

- Unconsolidated sedimentary aquifer (overbank deposits and the Columbia River Sand Aquifer);
- Troutdale gravel aquifer;
- Confining unit 1;
- Troutdale sandstone aquifer;
- Confining unit 2; and
- Sand and gravel aquifer.

The Base is located east of the western boundaries of confining unit 1; Troutdale Sandstone aquifer; confining unit 2; and the sand and gravel aquifer (Figure 4.1). To the west of the base, the Troutdale Sandstone aquifer pinches out; the sand and gravel aquifer interfingers with the confining unit 2; and the confining unit 1 and 2 form a single unit called undifferentiated fine-grained unit (Foster Wheeler Environmental Corporation, 1995). The Boring Lava unit may also be present as a perched aquifer in the area.

The unconsolidated sedimentary aquifer is approximately 200 to 275 feet thick and consists of the Columbia River Sand, overbank deposit, or the floodplain aquitard. At the Base, Columbia River Sand aquifer consists of micaceous siltstone and sandstone with wood fragments and gravel. Coarsening upward sequences characteristic of the channel deposit is common at the bottom of the unit. The overbank deposit (floodplain deposits) consists of light green-brown , yellow-brown silty clay and fine, sandy silt.

The Troutdale gravel aquifer is approximately 25 to 50 feet thick, consolidated, and consists of pebbly, cobbly conglomerates with greenish gray-brown, clayey, silty, sandy matrix. It is

DECEMBER 1995

hydraulically connected with the Columbia River Sand aquifer. Granitic and quartzite clasts are common in the unit and compromise approximately 30 percent of the rock fragments.

The confining unit 1 aquifer is about 200 feet thick and consists of dark gray-brown to gray-brown siltstone, claystone, and layers of vitric sandstone (up to 3 feet thick). A clay layer with high natural gamma signature is present at the bottom of the unit. Troutdale sandstone aquifer, a vitritic sandstone and conglomerate, unit is present in the Portland Basin and is approximately 50 feet thick. It consists of two units: the upper and the lower units. The upper unit is a vitric sandstone with silty clay lenses and a mixture of basaltic glass and clay. The lower unit consists of quartzite-bearing basaltic gravel conglomerates with a silty, sandy vitric-lithic matrix. Sand lenses of various thicknesses are present throughout the unit.

The confining unit 2 aquifer is about 25 feet thick and slopes toward the west. It consists of olive-gray, silty clay with lenses of basaltic sand and claystone layers at the bottom. The unit thickens toward the west and becomes part of the undifferentiated fine-grained unit. Confining unit 2 is hydraulically in communication with the Troutdale sandstone aquifer (Swanson et al., 1993).

The sand and gravel aquifer consists of a thick, silty, gravelly sand which fines downward. The unit is approximately 976 feet thick and slopes toward the northwest. The clay content increases toward the bottom of the unit. The upper unit of the sand and gravel aquifer is about 120 to 200 feet thick and consists of coarse-grained, consolidated, quartzite-bearing, basaltic gravel and cobbles with black vitric sand on top and muscovite laminae at the bottom. The lower unit is a fine-grained micaceous, quartzose, basaltic sand with blue-gray silt and sandy clay lenses.

The older Tertiary age rocks in the Portland Basin include the Columbia River Basalt Group, Skamania Volcanics, Goble Volcanics, Pittsburgh Bluff marine sediments, Scappoose Formations, and the Waverly Heights basalt. The older Tertiary rocks in the Portland Basin area are classified as a poor conductors of groundwater and are not used as water supply horizons.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 5.0 PERMITS

Prior to drilling activities, all fees, permits, or licenses required by ODEQ will be applied and/or paid. Notices of Intent to Drill will be filed with ODEQ as soon as possible to speed the WP implementation. As a part of mobilization activities, a general review of underground utility maps will be made, and Call First Utility Locations will be contacted to survey and clear utility locations in the vicinity of all drilling activities. Digging permits will be completed and submitted to the Civil Engineering Department for approval.

In the event any proposed drilling locations are found to interfere with buried utilities, the boring location(s) will be relocated as close as possible to the original location. Relocated drilling locations will be approved by the on-site geologist, HAZWRAP PM, and 142nd FG Civil Engineering Department. Proposed drilling locations will be staked in the field for inspection and approval by the 142nd FG Civil Engineering Department. This procedure will minimize the likelihood of damage to buried utilities. Once all activities have been completed at each specific drilling point, the location will be staked to facilitate any subsequent surveying.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 6.0 INVESTIGATIVE APPROACH

6.1 WORK PLAN AND DATA QUALITY OBJECTIVES

The main objectives of the RI is to acquire data of sufficient quality to (1) define the extent of confirmed environmental contamination; (2) prepare a screening risk assessment that addresses human health and the environment; (3) support informed decisions on remedial technologies proposed; and (4) to make recommendations for additional investigations and/or no further action decision documents (See Section 1.1). These objectives require quantification of the horizontal and vertical extent of contamination, the magnitude of contamination, and the migration of any contaminants from the sites.

The required data will be collected through integration of expedited sample collection, on-site laboratory, off-site laboratory chemical analyses, and data interpretation. The overall investigative approach to be implemented under this RI is presented in Figure 6.1. It illustrates an accelerated methodology for sample collection and interpretation. The goal is to obtain as much information as possible using innovative technologies and procedures, such a direct push technology (DPT), on-site laboratory analysis, and a real-time data management system to achieve the project objectives quickly and efficiently. Data quality will be maintained at the highest practical levels for the on-site laboratory. Off-site laboratory analyses will be performed to confirm the applicability and validity of the on-site analysis. A table has been generated for each site depicting the type and number of samples to be collected, the number of locations to be sampled, the nature of contaminants, the possible affected media, the sample collection methodology, and the required chemical analyses.

DQOs for the project require fixed-base laboratory data and field screening data. Fixed-base laboratory DQOs will meet definitive data quality requirements as defined in Data Quality Objectives Process for Superfund, Interim Final Guidance, (EPA/540/G-93/071, 1993), and guidance for planning for data collection in support of environmental decision making using the data quality objectives process (EPA QA/G-4, 1993). Fixed-base laboratory data reporting requirements include Contract Laboratory Program (CLP) type summary forms and supporting documentation required for a CLP data package without raw data. Field Gas Chromatograph/Mass Spectrometer (GC/MS) screening data will meet screening level data quality requirements as defined by EPA/540/G-93/071.

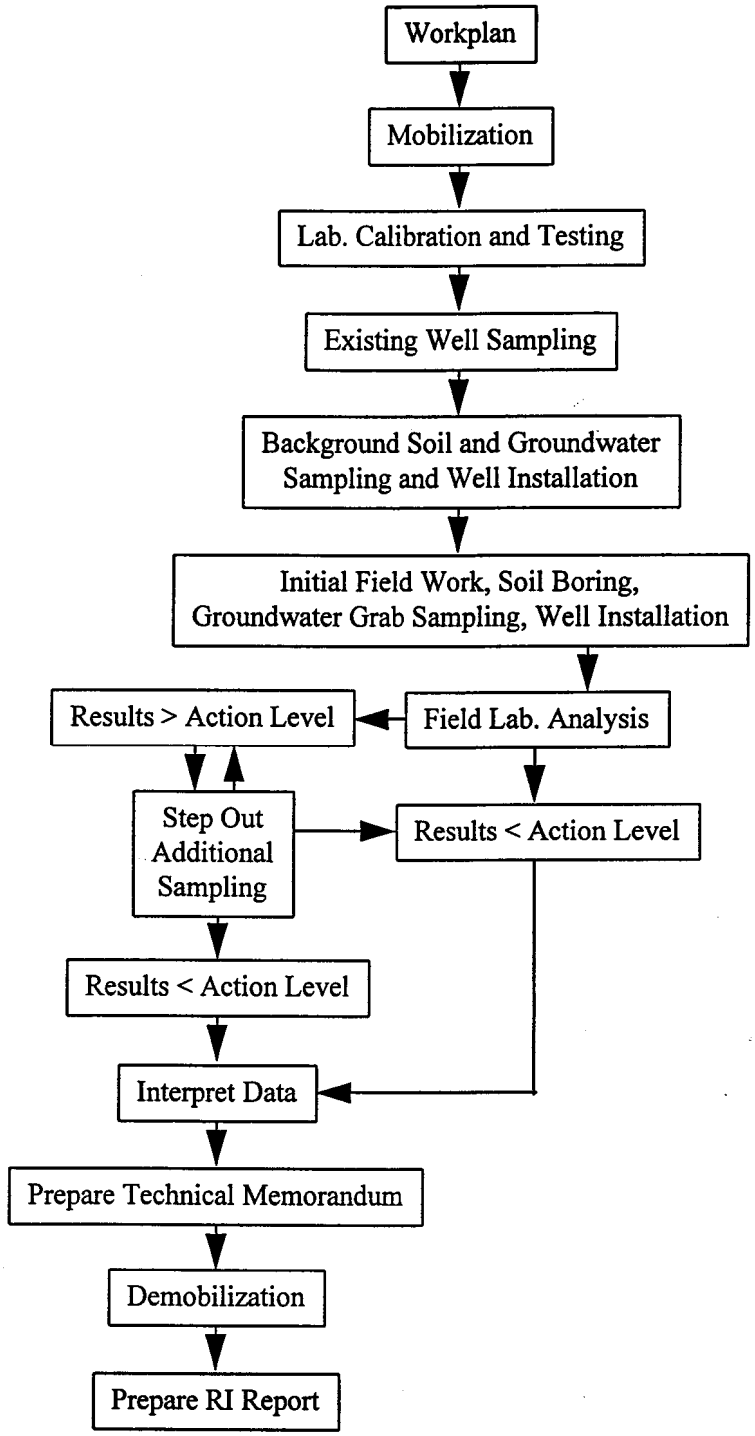

Figure 6.1 — **Overall RI Investigative Approach**
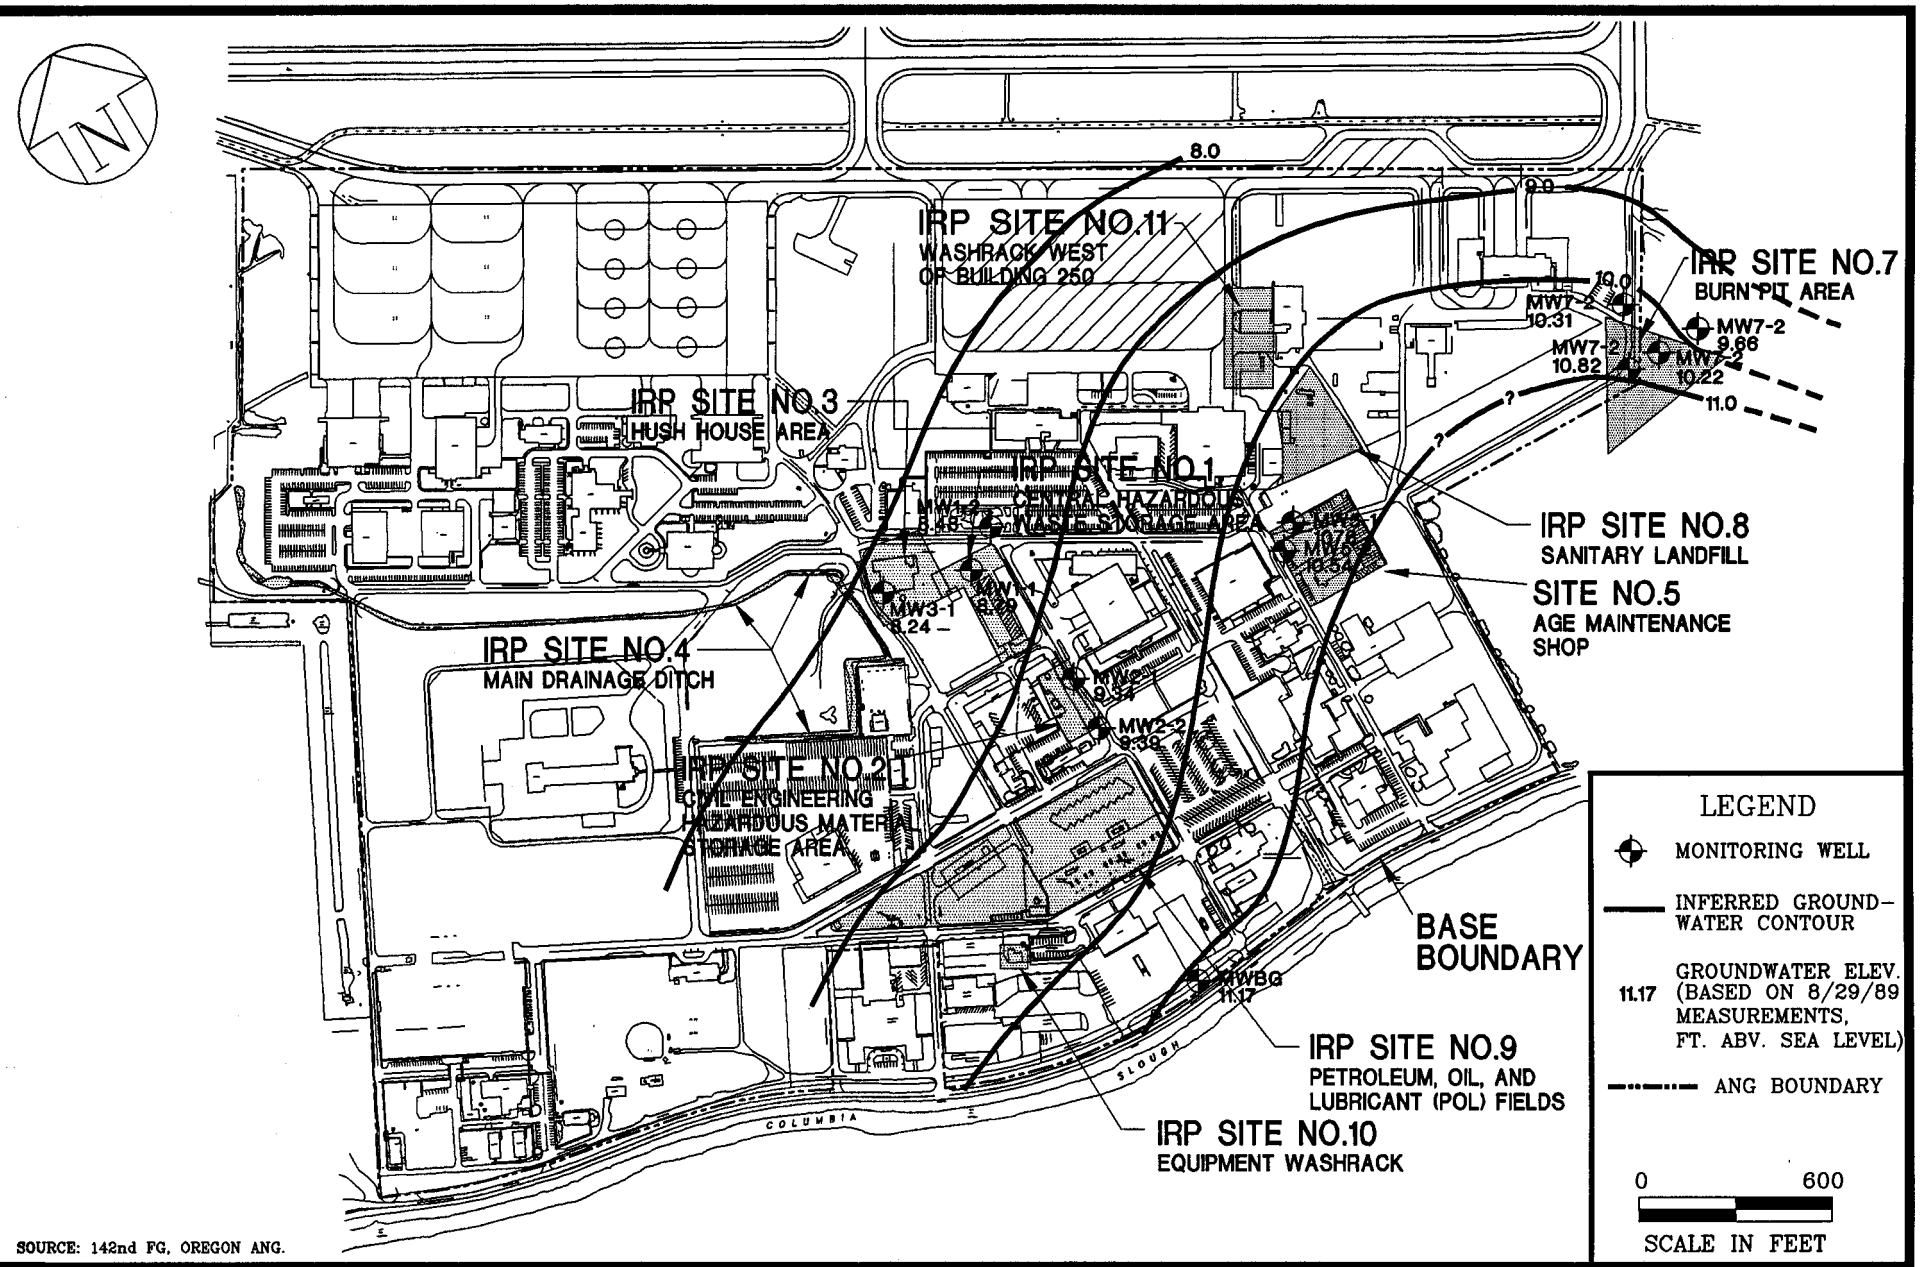
142nd Fighter Group, Oregon Air National Guard
Portland International Airport, Portland, Oregon

OPTECH Operational Technologies CORPORATION

DQOs for evaluation of data precision, accuracy, representativeness, comparability, and completeness are described in detail in the QAPP. Field generated data will be available at the end of each day to the project chemist, project manager, and HAZWRAP for evaluation. The evaluated data will then be returned to the field laboratory for correction, if required, and then be issued to HAZWRAP in a Technical Memorandum.

6.2 GENERAL APPROACH - SAMPLING STRATEGY AND RATIONALE



6.2.1 Groundwater Snapshot

In 1989, the shallow groundwater (5-15 ft bgs) across the Base was flowing in a north-northwest direction, based on groundwater elevation data taken from the piezometers and monitoring wells installed during the SI. Elevations were taken on August 29, 1989, and a potentiometric map was created using the groundwater levels (Figure 6.2). The flow at IRP Site No. 7 appears to have a northeastern component that is influenced by a drainage ditch located near the site.

The RI field program will be initiated by taking Base-wide water level measurements from existing piezometers and monitoring wells installed during previous investigations. The data will be used to construct a potentiometric map for the purpose of calculating the current groundwater gradient and flow direction. This map will be used to select the optimum of locations for the background soil borings, monitoring wells, and DPT points.

6.2.2 Project Action Goals

Chemical data obtained from the background samples collected during the RI will be evaluated and integrated with the background data collected during the SI to establish project action goals (PAGs). These action goals will be used to help establish the extent of contamination present at each site and to establish criteria to be incorporated into a screening risk assessment. These goals will establish the contaminant baseline, used to drive the decision process in deciding whether the extent of contamination has been delineated. In addition, chemical data will be processed through a database system that is linked to a mapping program, which will result in the construction of current isoconcentration maps. Data will be transferred to HAZWRAP electronically and presented as tables, graphs, maps, and narratives.

DECEMBER 1995

6.2.3 Primary, Secondary and Tertiary Phase Approach

After the PAGs are established, the investigation will proceed in determining the horizontal and vertical extent of contamination at each site. This will be accomplished by implementing a three phase investigative approach. The phases are identified as the primary point phase, the secondary point phase and the tertiary point phase. All phases will be implemented during one mobilization.

The investigation will begin with the installation of the primary soil (if applicable) and groundwater points at each site. All primary points will be driven to just below the top of the water table to collect groundwater samples. At least two soil samples and one groundwater sample will be collected from each primary point. Both soil (if applicable) and groundwater points will be collected from the same location. All samples will be collected and delivered to the on-site laboratory for analysis. Approximately five percent of all samples, independent of the site, will be collected as duplicate samples and delivered to an off-site laboratory for confirmational analyses. The analytical methods used by the off-site laboratory for VOC and SVOC analyses will be the same methods used in the on-site lab.

The on-site laboratory will be equipped with a gas chromatograph/mass spectrometer (GC/MS) Analyses conducted by the on-site lab will be for VOCs and SVOCs only, since they are the primary contaminants of concern at all sites. The on-site laboratory will allow the field team to make real time decisions and allow the investigation to proceed in an expedited manner to assess the extent of site specific contamination. At sites where secondary contaminants of concern are metals, TPH, or PCBs, analyses will be conducted at the off-site laboratory only. The small number of samples to be analyzed for the secondary contaminants do not support the costs of setting up the on-site laboratory for the analyses. The target analytes for each site are specifically discussed in this section.

After completing the installation of the primary points, the analytical results will be reviewed and compared to the established PAGs. This comparison will be conducted for the media investigated at each site to determine if the site has been fully delineated. As a result of the comparison, it will be determined whether to proceed with a secondary point phase.

If groundwater contamination is identified above the PAGs during the primary point phase, a vertical profile point will be installed to determine the vertical extent of groundwater contamination. The vertical profile point will be located closest to the primary point that identified the highest level of contamination . Vertical groundwater sample collection will begin

approximately 10 feet below the top of the water table and will continue up to a maximum depth of 40 feet bgs.

If compounds are found in the primary point phase above the PAGs (including the vertical profile), the secondary point phase will be implemented. These secondary points will be located downgradient of the primary points in attempt to fully define the area of contamination. These secondary points will only sample media that requires further delineation of compounds. It is anticipated that only groundwater will be sampled at secondary points because the locations will be further downgradient of source areas. However, if the results of the primary phase indicate that the soil unit has not been delineated, then soil samples will be collected from the secondary points. The sequence of the secondary phase will proceed in the same manner as for the primary point phase, with one exception. The samples collected during this phase will only be analyzed for the compounds identified above the PAGs during the primary phase.

Secondary vertical profile points will be installed after the completion of the secondary point phase investigation. These points will be implemented only if contamination is identified in the primary vertical profile points. The samples collected from these points will only be analyzed for the compounds identified above PAGs in the primary phase of vertical profiling and secondary points phase.

If the extent of contamination is undefined at the completion of the secondary phase, a tertiary phase may be performed. However, tertiary points are not illustrated in the basic primary and secondary phase field program (tables and figures) but will be implemented if secondary points remain unused after the basic program has been completed and contamination has still not been delineated.

Groundwater quality parameters that will be measured in the field at all groundwater sampling locations are temperature, conductivity, turbidity, and pH. Additional groundwater quality parameters that are useful for preparing the FS will be measured at up to 4 locations/site and at 2 background sites. These include field measurements of dissolved oxygen and carbon dioxide, and off-site laboratory analyses for nitrate, nitrite, ammonia, and phosphorus (reactive and total).

All soil samples will be screened for organic vapors using a photoionization detector (PID). If the soil media is investigated at a site, soil quality parameters useful for preparing the Feasibility Study will collected at up to four soil samples/site and two background samples. This includes

samples collected for off-site laboratory analyses of nitrate, nitrite, and phosphorus (reactive and total); field meters will be used to collect soil gas measurements of oxygen and carbon dioxide.

At the end of each phase the data and recommendations on how to proceed will be presented to HAZWRAP and the HQ ANG/CEVR. Agreement will be reached before initiating the next phase of investigation at a given site.

6.2.4 Sediment and Surface Water Sampling

Sediment and surface water samples will be collected from specific sites for risk assessment purposes. The sampling will be done independently of the background and phase investigations.

6.2.5 Antecedent Water Level Measurement

In addition to the initial groundwater snapshot, at least two Base-wide snapshots are anticipated to be conducted. This will occur after the installation of all monitoring wells. Water level measurements will be taken in association with normal field activities; after well installation, before and after well development, and prior to sampling events. The water level elevations will be used to calculate the groundwater gradient and the flow direction, and help in the location and collection of groundwater samples.

6.2.6 Surveying

Sediment, soil boring, surface water, groundwater grab sample locations, and permanent monitoring wells will be surveyed by a surveyor registered in the State of Oregon. Horizontal accuracy shall be plus or minus 0.1 ft and vertical accuracy shall be within plus or minus 0.01 ft. All surveyed data will be presented in the X, Y and Z axes.

6.2.7 Analytical Methods

The primary contaminants of concern are associated with fuels (gasoline and JP-4) and solvents as determined by historical records search and results of the SI. Secondary contaminants of concern are considered to be metals, TPH and PCBs. The on-site field laboratory will be equipped to analyze samples for VOCs and SVOCs using a GC/MS to provide qualitative and quantitative results. Both soil and groundwater samples will be analyzed at the on-site laboratory. The minimum QA/QC requirements that will be followed are specified in DOE/HWP-65R1 for

HAZWRAP Level B screening. The objective for on-site laboratory analysis for this project is to provide high quality data on which to base real-time field decisions. In order to achieve this objective, additional QC samples and protocols, not required under HAZWRAP Level B field screening criteria, will be employed as described in the QAPP.

Fixed-base laboratory analyses will be conducted in accordance with HAZWRAP Level C protocols. SW-846 Method 8260 will be used for soil and water VOC analyses. SW-846 Method 8270 will be used and soil and water SVOC analyses. SW-846 Method 8080 will be used for soil and water PCB analyses. The CLP analyte lists located in the QAPP (Tables 4.1- 4.5) will be used when performing VOC, SVOC, and PCB methods. SW-846 Method 6010 will be used for soil and water metals analyses. SW-846 Method 7470 will be used for mercury analysis (water) and SW-846 Method 7471 will be used for mercury analysis (soil). TPH will be analyzed according to modified SW-846 Method 8015 for soil only. Details concerning the analytical methods and detection limits are provided in the QAPP (Appendix B).

Quality control samples (soil and water) will be collected and analyzed by field GC/MS and fixed-base laboratories. The types and the frequency of the QC samples for field and fixed-base laboratories are as follows:

- Equipment blanks; 10% of samples/matrix/equipment;
- Field blanks; 1/source/event;
- Duplicates; 10% of samples/matrix;
- Matrix spike/Matrix spike duplicates; 5% of samples/matrix; and
- Trip blanks; one per sample shipment cooler containing VOC samples.

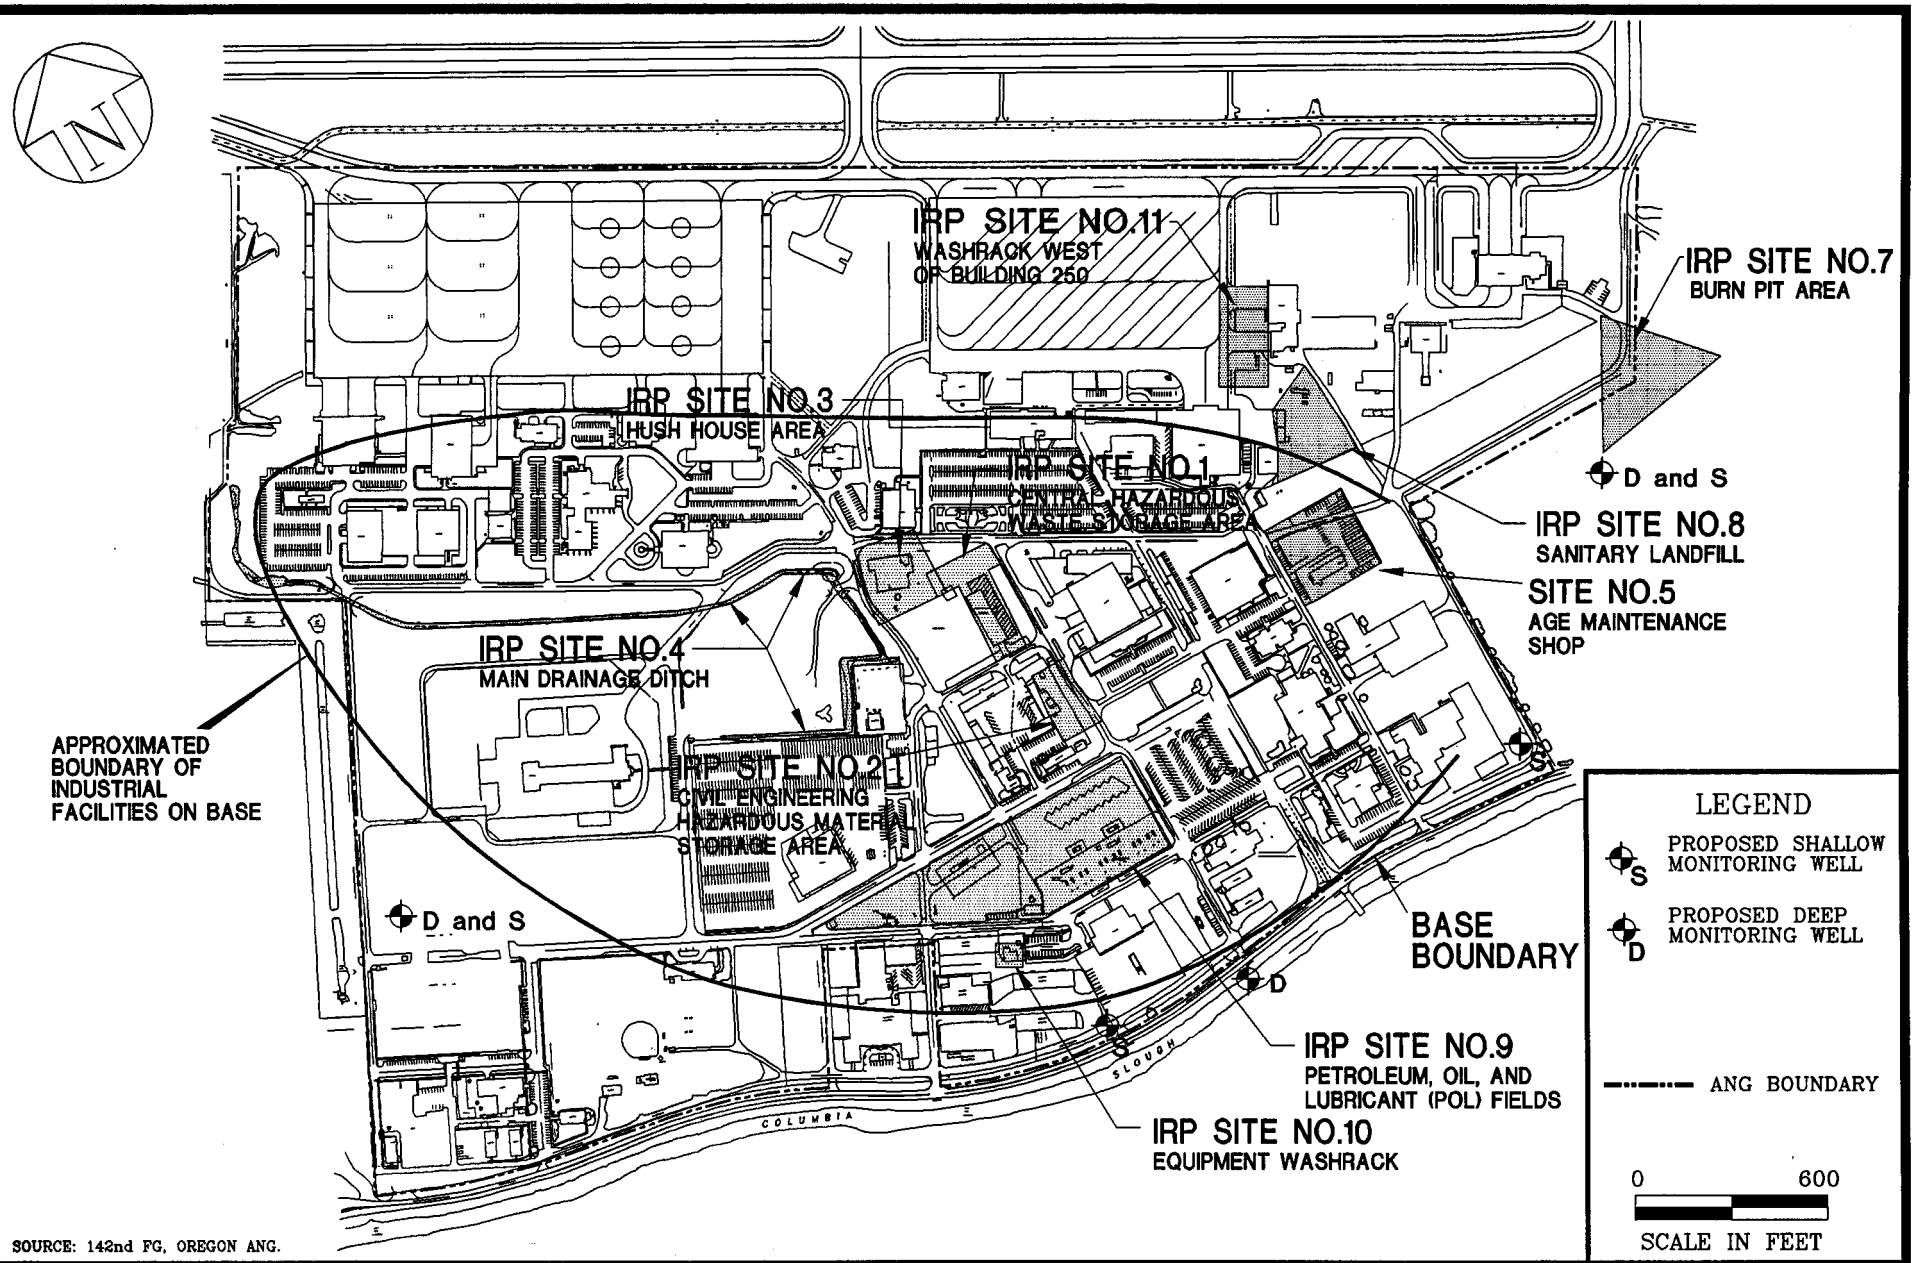
Fixed-base laboratory soil and groundwater samples for nitrate, nitrite, ammonia, and phos phorus (total and reactive) analyses will have no associated QC sampling performed.

6.2.8 Geotechnical Samples

Two sets of geotechnical samples will be collected at each site where soil is being investigated. These samples will be measured for grain size analysis (ASTM D422) and permeability (ASTM D2434). If the samples are primarily clay and silt the Atterberg Liquid Limit, Plastic Limit, and Plasticity Index (ASTM 4318) will also be measured.

6.2.9 Aquifer Tests

Aquifer slug tests will be performed on all monitoring wells installed as part of this field effort. Rising head tests will be performed by depressing the water table with pressure or pumping, then monitoring recovery of the aquifer with a pressure transducer. The data measured from the pressure transducer will be recorded on a data-logger recorder. This data will be analyzed using the Bower and Rice (1976) or Hvorslev (1951) methods for unconfined aquifers.



6.3 RI SITE-SPECIFIC SAMPLING STRATEGY

6.3.1 Base Background Investigation

Background soil and groundwater samples will be collected as part of the RI. Results of the background investigation conducted during this mobilization will be incorporated into the background data collected in the SI to establish PAGs. It also allows a comparison of data collected from individual sites with the background information to establish criteria for the screening risk assessment, and if necessary, remedial actions. A detailed description of the background sampling activities and results are provided in Subsection 3.2.11 of this document.

A total of seven monitoring wells will be drilled and installed at five separate locations (two cluster locations) on and off the Base for the purpose of collecting both soil and groundwater data for the background study (Figure 6.3). Access for offsite loctions will be obtained by Base personnel. Of the seven wells to be drilled four will be completed as shallow wells screened across the water table and three will be completed as deep wells with the bottom of the screen set at 40 feet. Soil samples from all the shallow wells will be collected continuously from the surface to the water table (approximately 5-10 ft) for the purpose of obtaining lithologic information. At the locations where the deep well is located adjacent to a shallow well, continuous soil sampling will be initiated at the water table. Soil samples will be screened with a PID in the field before any sample is collected for the laboratory analyses. If contamination is identified by the PID field screening, the boring will be appropriately abandoned and a new location selected.

Three soil samples will be collected from a boring at each of the five separate locations. One sample will be collected from the surface (0 to 6 inches) to satisfy the risk assessment requirements. A second sample will be collected from an intermediate depth between the surface

and approximately five feet based on field screening, and a third sample will be collected from immediately above the water table.

Two rounds of groundwater samples will be collected from the background monitoring wells installed as part of this field effort and existing background well MWBG. The first round will be collected after the installation of the background monitoring wells. The second round will be collected at the end of the RI field effort. All soil and groundwater samples will be analyzed by the field laboratory for VOCs and SVOCs. A selected number of samples analyzed for VOCs and SVOCs at the on-site lab (approximately 5%) will also be analyzed at the fixed-base laboratory (refer to QAPP). At least one sample from each background groundwater sampling round will go to the fixed-base laboratory for analysis. All samples collected during the background investigation will also be analyzed at the fixed-base laboratory for PPMs (filtered and unfiltered), PCBs, and TPH (soils only). The background soil and groundwater sampling program at the Base is presented in Table 6.1.

Two background soil locations will also be sampled for soil quality parameters including nitrate, nitrite, ammonia, and phosphorus (total and reactive). Soil gas measurements of oxygen and carbon dioxide will be collected at these locations. Two background groundwater locations will be sampled for water quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.

6.3.2 IRP Site No. 1 - Central Hazardous Waste Storage Area

IRP Site No. 1 is located at the southwest corner of the intersection of O'Conner Way and Hampshire Blvd., near Bldg. 1131 (Figure 6.4). IRP Site No. 1 was used to store 55-gal drums of waste oils, fuels, solvents, shop waste, and electrical transformers. According to the results of the SI, accidental spills or leaks from containers have impacted the groundwater in an area adjacent to Bldg. 1131. Two areas of concern will be the target of the RI. The first area is located northeast of Bldg. 1131 where high concentrations of methylene chloride and bromochloromethane were detected at 1,500 μg/L and 140,000 μg/L, respectively, in the groundwater samples collected from MW1-1. The second area is located southwest of Bldg. 1131 where the compounds bromochloromethane and methylene chloride were detected in soil samples collected at the water table from SB1E-14.

A risk assessment conducted after the SI indicates the soils at IRP Site No. 1 pose no threat to human health and the environment. Therefore, only the groundwater will be investigated as part

of the RI. The water table was encountered at a depth of approximately 5 to 7 ft bgs during the SI. The proposed scope of work to be conducted under this WP is provided below.

The primary phase will consist of up to seven points in an initial attempt to delineate the extent of groundwater contamination. Four of the points will be located in the area of MW1-1, and three points will be placed in the area southwest of Bldg. 1131 in the vicinity of SB1E-14.

The analytical results will be compared to the established PAGs. If contamination is identified above an action goal, up to seven secondary points and three primary vertical profile points will then be performed. The analyses to be conducted on the secondary points will be for the compounds detected in the primary phase only. Currently, four secondary points and two primary vertical points are designated for the northeast area, while three secondary points and one primary vertical point are designated for the southwest area. However, it is possible that, based on field results, some of the points designated for one area may not be needed and may be moved to the

other areas where needed. This decision will be made in the field with the concurrence of HAZWRAP and the HQ ANG/CEVR.

Depending on the results of the previous phases, an additional two secondary vertical profile points, one for each area, may be available. One groundwater sample will be collected from each of the points terminated at the water table . Up to three samples will be collected from the vertical profile points. The existing monitoring wells at the site, MW1-1 and MW1-2, will also be purged and sampled. All groundwater samples will be analyzed in the field laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) will be analyzed by the fixed-base laboratory. IRP Site No. 1 groundwater sampling program is presented in Table 6.2.

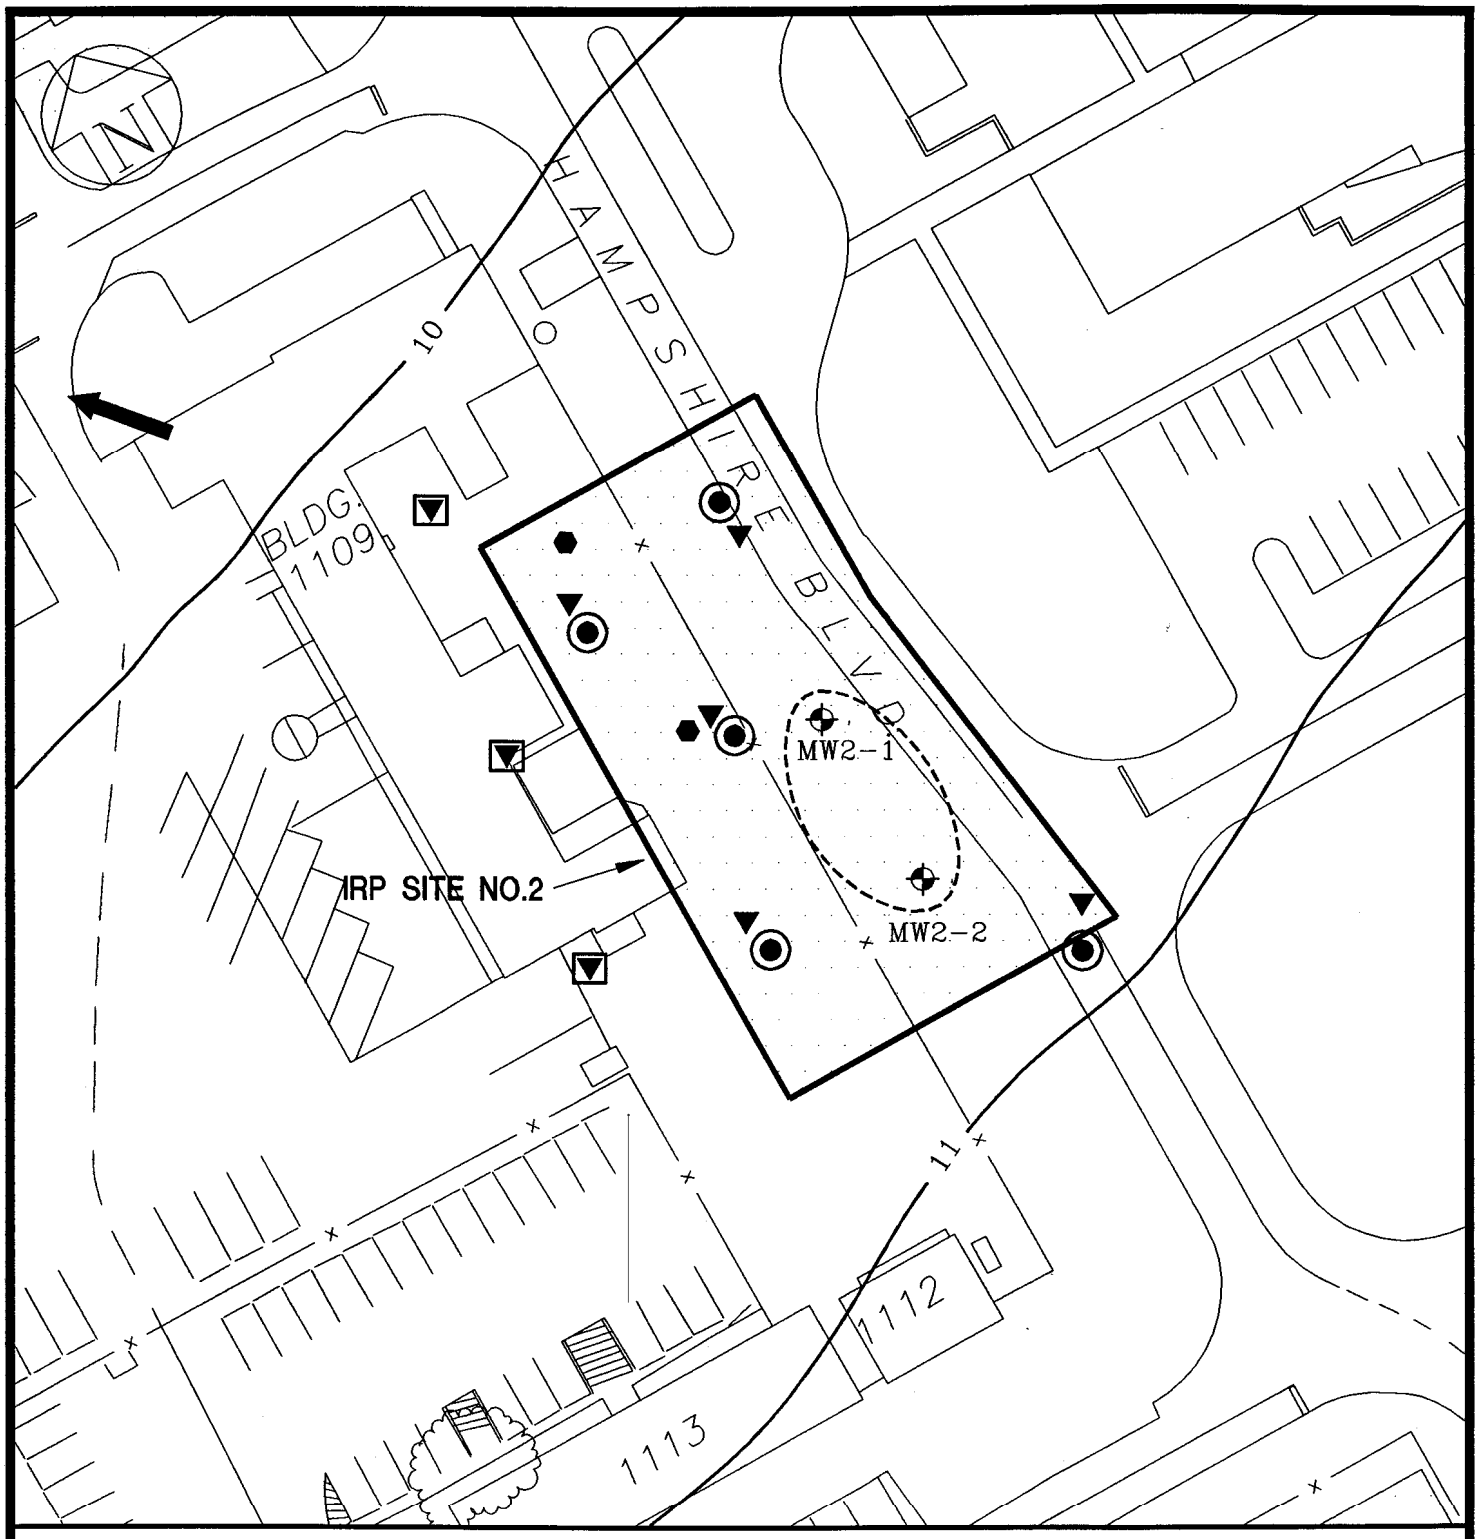
Four groundwater locations will be sampled for water quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.



6.3.3 IRP Site No. 2 - Civil Engineering Hazardous Materials Storage Area

IRP Site No. 2 is the former Civil Engineering Hazardous Materials Storage Area located adjacent to Bldg. 1109 (Figure 6.5). IRP Site No. 2 consisted of an open walled shed with a gravel floor. Drums of chemicals, including solvents and methyl ethyl ketone, were stored on wooden pallets. Accidental spills or leaks from containers have impacted the groundwater and possibly the soil. According to the SI, source areas for soil contamination have not been fully delineated and characterized. Results of analyses conducted on groundwater samples collected from the two monitor wells installed at the site indicate up to 710 μg/L of trichloroethene . The water table was encountered at a depth of approximately 5 to 7 ft bgs (SAIC, 1991). Subsection 3.2.2 provides additional information regarding the SI results. Both the soil and groundwater will be investigated at this site in the RI.

The primary phase at IRP Site No. 2 will consist of up to five points positioned upgradient and downgradient of the two contaminated monitoring wells. Two soil samples per primary point will be collected and submitted to the on-site laboratory for analyses. One sample will be collected from the surface to approximately five feet bgs and will be selected based on the highest PID reading, and one sample will be collected from the interval immediately above the water table. One groundwater sample per point will be collected from just below the top of the water table for on-site laboratory analyses. In addition, three surface soil samples will be collected at the site at intervals of 0 to 6 inches.

The analytical results will be compared to the established PAGs. If contamination is identified above a PAG, up to three secondary points and two primary vertical profile points will then be emplaced. The analyses to be conducted on the secondary points will be for the compounds detected in the primary phase only. All the locations to be conducted in this phase will be placed downgradient of the two monitoring wells.

One groundwater sample each will be collected from the points terminated at the water table. Up to three samples will be collected from each of the vertical profile points. The existing monitoring wells at the site, MW2-1 and MW2-2, will also be purged and sampled. All samples will be analyzed in the on-site laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) will be analyzed by the fixed-base laboratory. IRP Site No. 2 groundwater sampling program is presented in Table 6.3.

Soil gas measurements of oxygen and carbon dioxide will be collected at these locations. Four groundwater locations will be sampled for water quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.

6.3.4 IRP Site No. 3 - Hush House Area

IRP Site No. 3 is located on the southeast corner of the intersection of O'Conner Way and Carey Street. There are two areas of concern associated with IRP Site No. 3. One of the areas is southwest of the former Hush House (Figure 6.6), where a former oil/water separator associated with the Hush House was located and is designated as Area B. The second area is northeast of the former Hush House where construction in 1994 discovered potential soil and groundwater contamination; the area is designated as Area C. Soil contamination was noted to occur at depths up to 8 ft bgs and was in contact with the groundwater. The water table was encountered at approximately 6 to 7 ft bgs. Subsection 3.2.3 provides additional information regarding the SI

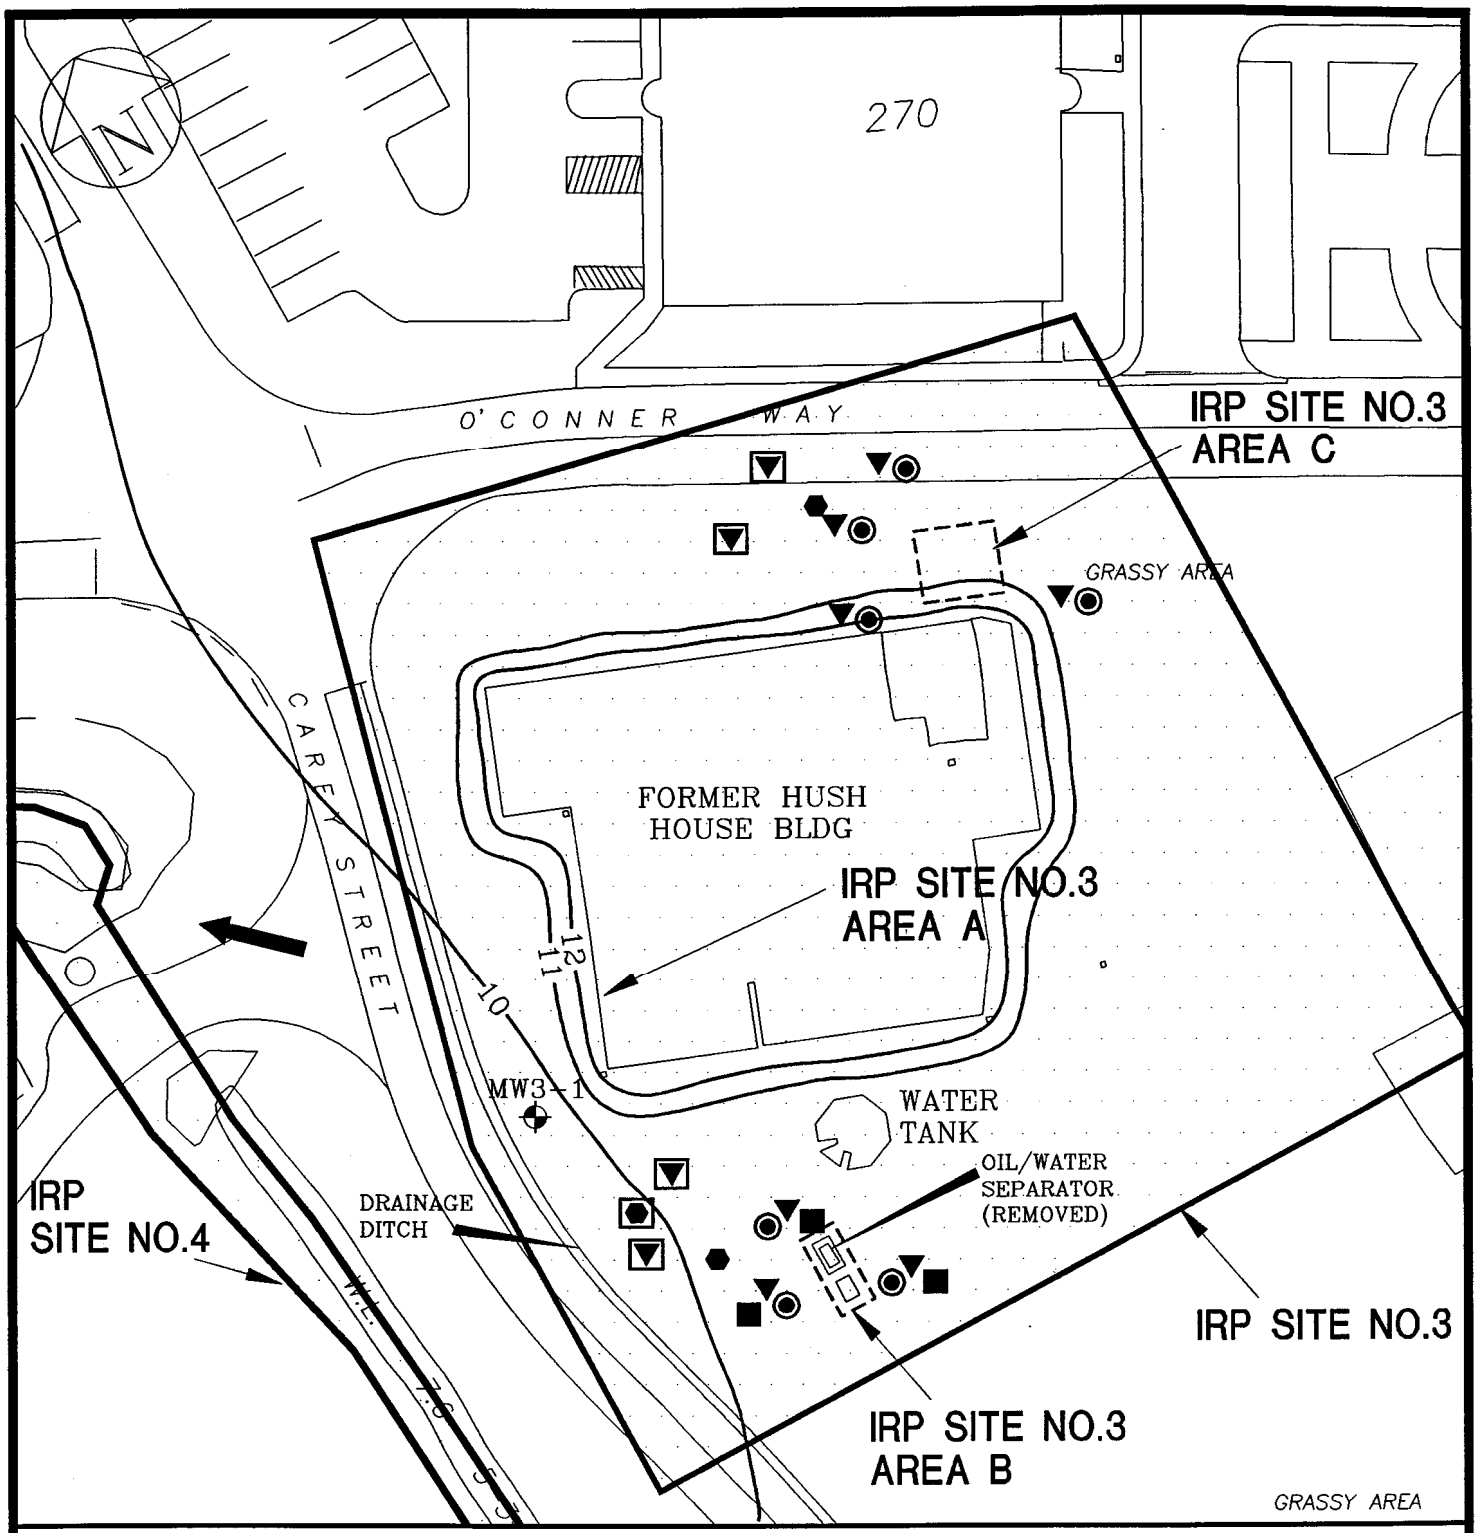

FIGURE 6.6

PL_FIG\ST_3-4

OPERATIONAL TECHNOLOGIES CORPORATION

DECEMBER 1995

and past construction activities. Both soil and groundwater will be investigated at both areas of concern in the RI. The proposed scope of work to be conducted under this WP is provided below.

The primary phase will consist of up to seven points in an initial attempt to delineate the extent of soil and groundwater contamination. Three of the points will be located in the area of the oil/water separator and four points will be placed in the area northeast of the former Hush House.

Two soil samples per primary point will collected and submitted to the on-site laboratory for analyses. One sample will be collected from the surface to approximately five feet bgs and will be selected based on the highest PID reading, and one sample will be collected from the interval immediately above the water table. One groundwater sample per point will be collected from just below the top of the water table for on-site laboratory analyses. To support the risk screening assessment, three surface soil samples will be collected from the site at intervals of 0 to 6 inches.

The analytical results will be compared to the established PAGs. If contamination is identified above a PAG then up to four secondary points and two primary vertical profile points will be completed. The analyses to be conducted on the secondary points will be for the compounds detected in the primary phase only. Currently, two secondary points and one primary vertical points are designated for the southwest area and two secondary points and one primary vertical point are designated for the northeast area. However, it is possible that based on field results that some of the points designated for one area may not be needed and may be moved to the other areas where needed. This decision will be made in the field with the concurrence of HAZWRAP and the HQ ANG/CEVR.

One groundwater sample will be collected from each of the points terminated at the water tables. Up to three samples will be collected from the vertical profile points. The existing monitoring well at the site, MW3-1, will also be purged and sampled. All samples will be analyzed in the field laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) will be analyzed by the fixed-base laboratory. Additionally, all soil samples will be analyzed at the fixed-base laboratory for PPM and TPH. All groundwater samples will be analyzed at the fixe-base laboratory for PPM (filtered and unfiltered) . IRP Site No.3 sampling program is presented in Table 6.4.

Four soil locations will also be sampled for soil quality parameters including nitrate, nitrite, ammonia, and phosphorus (total and reactive). Soil gas measurements of oxygen and carbon dioxide will be collected at these locations. Four groundwater locations will be sampled for water

quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.

6.3.5 IRP Site No. 4 - Main Drainage Ditch

IRP Site No. 4 is located in the west central portion of the Base, extending from an area near the parking lot of Bldg. 455 to a point on the northwest Base boundary (Figure 6.7). The Main Drainage Ditch collects overland flow and storm water from the majority of the Base. Fuel spills have occurred in the past that may have reached the ditch. An oil sheen has been observed on surface waters in the ditch as recently as April 1993. During previous investigations, sediment sampling along the ditch showed low concentrations of TPH (< 25 mg/kg) and detection of five metals in sediment samples. No surface water samples have been collected. Based on results from the SI, sediment and surface water sampling are recommended at IRP Site No. 4. See Subsection 3.2.4 for additional information. To characterize the extent and nature of contaminants in the sediments, up to seven sediment samples will be collected. Also, seven surface water samples will be collected, if present, along the length of the ditch.

All sediment and surface water samples will be analyzed by the field laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) may be analyzed by the fixed-base laboratory according to the QAPP. All sediment samples will also be analyzed at the fixed-base laboratory for PPMs, PCBs, and TPH. All surface water samples will also be analyzed at the fixed-base laboratory for PPMs (unfiltered) and PCBs. IRP Site No. 4 sediment and surface water sampling program is presented in Table 6.5.

Four sediment samples will also be sampled for soil quality parameters including nitrate, nitrite, ammonia, and phosphorus (total and reactive).

6.3.6 IRP Site No. 5 - AGE Maintenance Shop

IRP Site No. 5 is the AGE Maintenance Shop located at Bldg 160 (Figure 6.8) near the intersection of O'Conner Way and Carl Street. The site is split into three areas: IRP Site No. 5 Area A, the North Fence Area; IRP Site No. 5 Area B, the Former UST Area; and IRP Site No. 5 Area C, the South Fence Area. Wastes generated by the AGE Maintenance Shop include spent battery acid, solvents, lubricants, antifreeze, cleaning solutions, and automotive fluids. These wastes were possibly disposed along the North and South Fence Areas (IRP Sites No. 5 Area A and Area C).

IRP Site No. 5 Area A was investigated during the SI. The results indicated slightly elevated concentrations of cadmium, lead, and zinc in soils compared to background. Trichoroethene (6

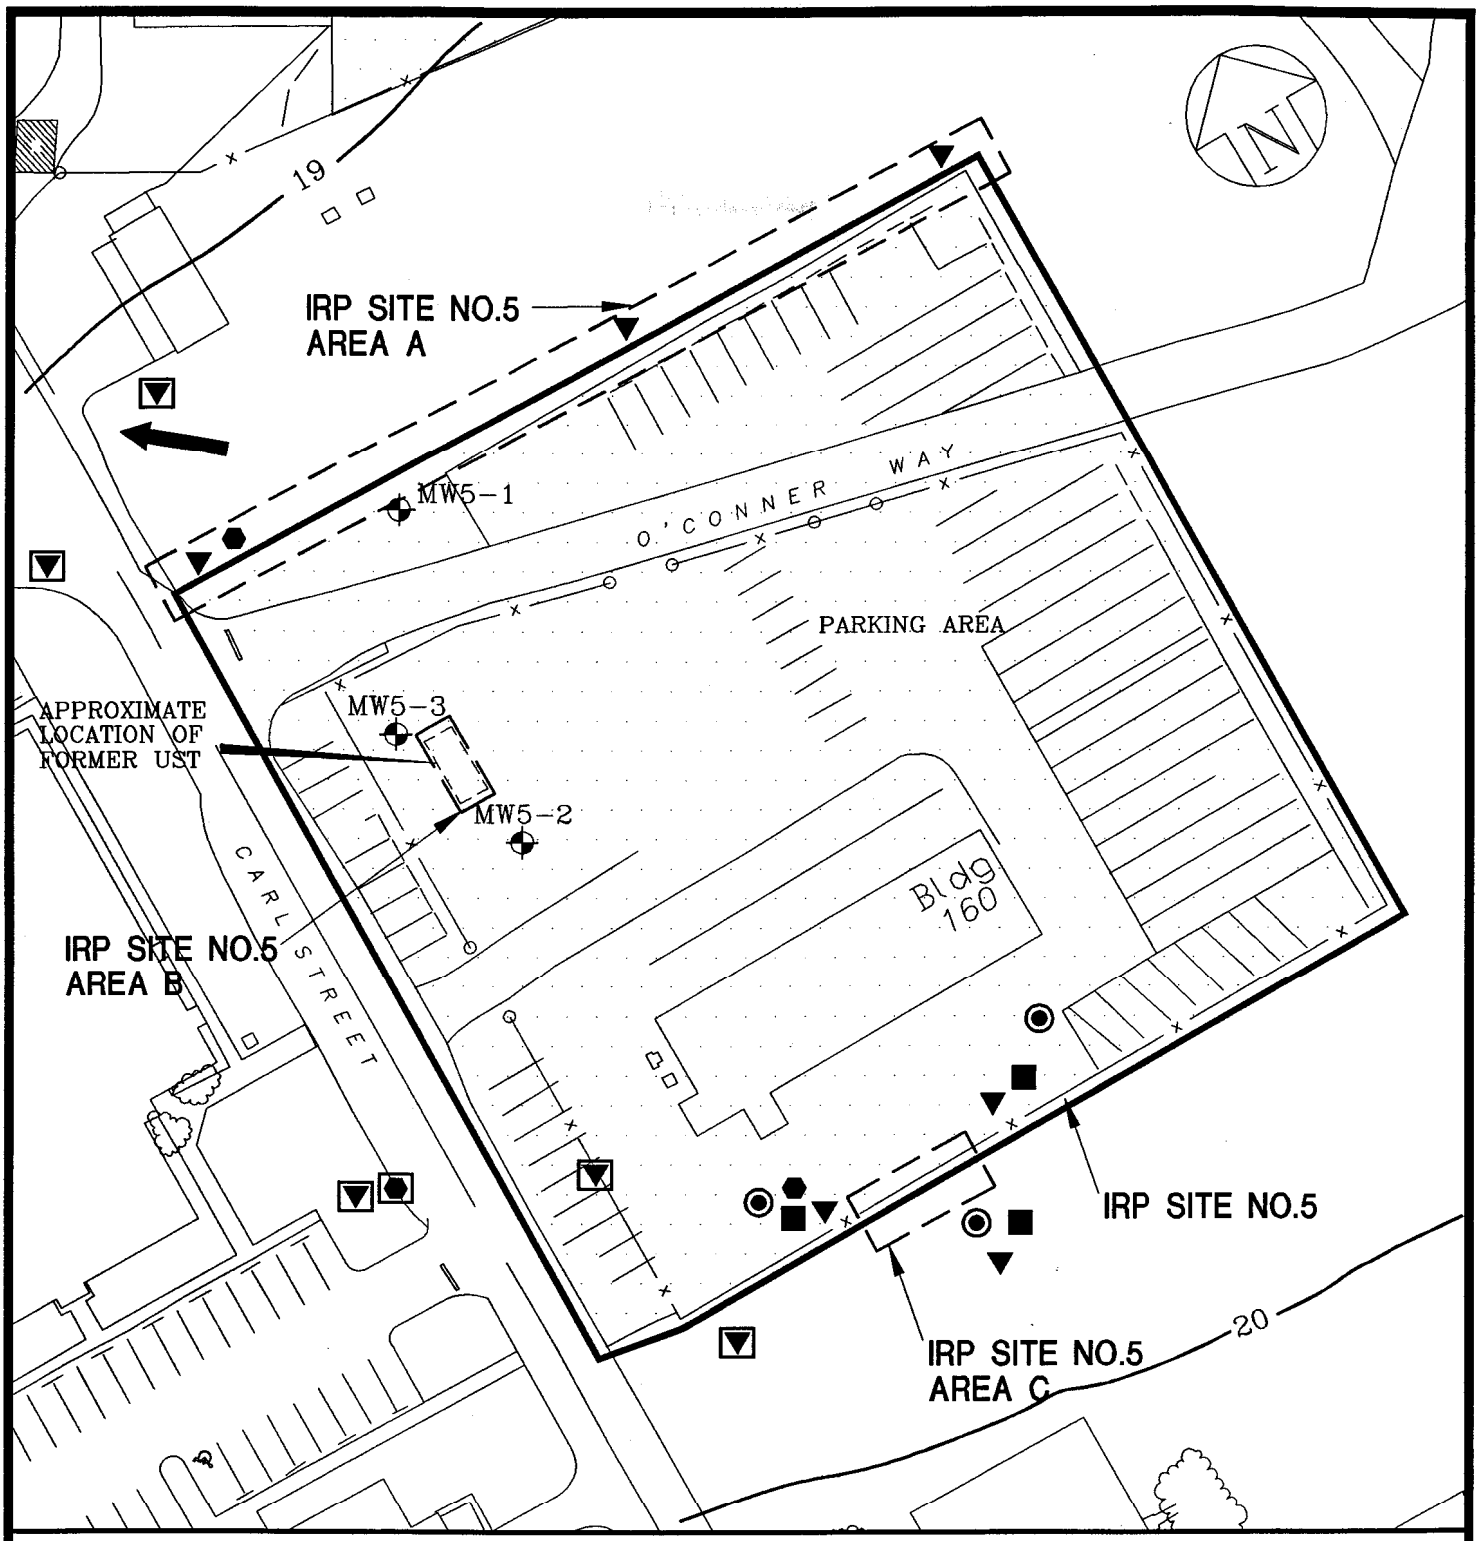

FIGURE 6.8

OPTECH
OPERATIONAL TECHNOLOGIES CORPORATION

DECEMBER 1995

μg/L) and sulfate (42 milligrams/liter (mg/L)) were detected in groundwater from MW5-1. Based on the SI findings and the preliminary risk characterization, the SI recommended that only the groundwater be further investigated in the site area.

IRP Site No. 5 Area B was investigated and remediated as part of the HQ ANG/CEVR's Rapid Response Program and will not be addressed under the RI.

IRP Site No. 5 Area C was not investigated during the SI. During a site visit in 1993, stressed vegetation was noted along the fence. The RI will address soil and groundwater in this site area.

The water table occurs at a depth of approximately 5 to 7 ft bgs (SAIC, 1991). See Subsection 3.2.5 for additional information regarding the SI results.

The primary phase will consist of up to six points in an initial attempt to delineate the extent of soil (5C only) and groundwater contamination. Three of the points will be located in the 5C area and three points will be placed in the 5A area. Two soil samples per primary point (5C only) will be collected and submitted to the on-site laboratory for analyses. One sample will be collected from the surface to approximately five feet bgs and will be selected based on the highest PID reading, and one sample will be collected from the interval immediately above the water table. One groundwater sample per point, both 5A and 5C areas, will be collected from just below the top of the water table for on-site laboratory analyses. To support the risk screening assessment, three surface soil samples will be collected from the site at intervals of 0 to 6 inches (5C only).

The analytical results will be compared to the established project action goals. If contamination is identified above an action goal, up to five secondary points and two primary vertical profile points will then be performed. Currently, two secondary points and one primary vertical point are designated for the 5A area while three secondary points and one primary vertical point are designated for the 5C area. However, it is possible that, based on field results, some of the points designated for one area may not be needed and may be moved to other areas where needed. This decision will be made in the field with the concurrence of HAZWRAP and the HQ ANG/CEVR.

Depending on the results of the previous phases, an additional secondary vertical profile point for the 5C area may be installed. One groundwater sample will be collected from each of the points terminated at the water table. Up to three samples will be collected from the vertical profile points. Existing monitoring well MW5-1 will also be purged and sampled. All samples will be

analyzed in the field laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) will be analyzed by the fixed-base laboratory. All samples collected from Site 5 Area C will be analyzed at the fixed-base laboratory for PPMs. Both filtered and unfiltered groundwater samples will be collected for PPM analyses. IRP Site No. 5 sampling program is presented in Table 6.6.

*PPM analyses will be conducted on samples collected from Site 5 Area C and will include filtered & unfiltered groundwater samples.

Four soil locations will also be sampled for soil quality parameters including nitrate, nitrite, ammonia, and phosphorus (total and reactive). Soil gas measurements of oxygen and carbon dioxide will be collected at these locations. Four groundwater locations will be sampled for water quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.

6.3.7 IRP Site No. 7 - Burn Pit Area

IRP Site No. 7 is located outside the eastern Base boundary, east of Bldg. 210 (Figure 6.9). The Burn Pit was used for fire training exercises between 1957 and 1978. It was estimated (SAIC, 1991) that several thousand gallons of waste oils, jet fuel (JP-4), solvents, and flammable liquids were burned in the pit each year. The soil gas survey conducted during the SI indicated the potential for contamination at the site, including fuel components and solvents. However, the soil and groundwater samples collected during the SI indicated very low levels of contamination.

Based on the results of the SI, the RI will concentrate on a limited number of soil and groundwater points. The site area is now covered with gravel. The water table was encountered at a depth of approximately 9 to 15 ft bgs (SAIC, 1991). See Subsection 3.2.6 for additional information. The proposed scope of work to be conducted under this WP is provided below.

The primary phase will consist of up to two points. Two soil samples per primary point will collected and submitted to the on-site laboratory for analyses. One sample will be collected from the surface to approximately five ft bgs and will be selected based on the highest PID reading, and one sample will be collected from the interval immediately above the water table. One groundwater sample per point will be collected from just below the top of the water table for on-site laboratory analyses. To support the risk screening assessment, two surface soil samples will be collected from the site at intervals of 0 to 6 inches.

The analytical results will be compared to the established project action goals. If contamination is identified above an action goal, up to two secondary points will then be performed to delineate the plume. The analyses to be conducted on the secondary points will be for the compounds detected in the primary phase only. No vertical profile points are proposed for this site.

One groundwater sample will be collected from the primary and secondary points associated with this site. The existing monitoring wells at the site, MW7-1, MW7-2 and MW7-3 will also be purged and sampled.

All samples will be analyzed in the on-site laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) will be analyzed by the fixed-base laboratory. IRP Site No. 7 sampling program is presented in Table 6.7.

Four soil locations will also be sampled for soil quality parameters including nitrate, nitrite, ammonia, and phosphorus (total and reactive). Soil gas measurements of oxygen and carbon dioxide will be collected at these locations. Four groundwater locations will be sampled for water quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.

6.3.8 IRP Site No. 8 - Sanitary Landfill

The location of IRP Site No. 8 is thought to be immediately east of Bldgs 235 and 240 (Figure 6.10). The original site area was estimated to be one acre in size and was reported to have received building and shop refuse, paint cans, oil residues, batteries, and waste paper. The landfill was estimated to be in operation from 1949 to 1956. During previous investigations, aerial photographs were reviewed and geophysical surveys and trenching were conducted to identify the location of the landfill and waste materials. No evidence of the landfill was discovered by the intrusive activities. The RI recommended conducting additional geophysical surveys and limited sampling of the groundwater. The water table is estimated to occur at a depth

DECEMBER 1995

of approximately 6 to 9 ft bgs. See Subsection 3.2.7 for additional information. To locate the former sanitary landfill and the areas to be investigated, all available historical photographs will be acquired and reviewed. Photographs will be acquired from the Base, U.S. Army Corp of Engineers, U.S. Geological Survey, and private companies. The photographs will be used to identify the disturbed areas indicative of landfill activities at the site area. These disturbed areas will be then be marked in the field to conduct the geophysical surveys.

Three types of geophysical surveys are proposed to be performed at the site. Geophysical surveys will include a magnetometer survey (MAG), an electromagnetic survey (EMS), and a ground penetrating radar survey (GPR). The MAG survey will identify the buried metallic materials while the EMS will measure the differences between conductivities of the buried solid waste and the surrounding soils. The GPR survey will identify the natural subsurface features and contacts between the disturbed and undisturbed materials in the ground.

The geophysical surveys will be performed on a 30 ft by 30 ft grid and are expected to cover an area approximately 250 ft by 350 ft. The MAG and the GPR survey measurements will be collected along the grid lines, and the EMS measurements will be collected at the grid nodes. After the geophysical data has been interpreted and reviewed, anomalies suspected of being representative of the landfill will be marked in the field.

At the completion of the geophysical activities at the site and if the landfill can be identified, three primary points will be conducted downgradient of the site. The points will be located beyond the landfill boundaries as defined by the geophysical survey. One groundwater sample from each point will be collected. The sample will be collected from just below the water table. All groundwater samples will be analyzed by the field laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) may be analyzed by the fixed-base laboratory according to the QAPP. All groundwater samples will also be analyzed at the fixed-base laboratory for PPMs (filtered and unfiltered) and PCBs. IRP Site No. 8 groundwater sampling program is presented in Table 6.8.

If groundwater sampling is conducted three groundwater locations will be sampled for water quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.

6.3.9 IRP Site No. 9 - Petroleum, Oil and, and Lubricants (POL) Facility

IRP Site No. 9 consists of two separate source areas: IRP Site No. 9 Area A which contained the former POL facility, a former JP-4 dispensing area on the east side, and a diesel dispensing area on the west side, and Site No. 9 Area B, the former diesel fuel dispensing area (Figure 6.11). IRP Site No. 9 Area A is bounded by Boyington Avenue on the north, Johnson Avenue on the south, and Hampshire Boulevard on the east. The site contained twelve 25,000-gal USTs and one smaller waste oil tank. Soil contamination was discovered at the site area during construction activities in 1991. Stained soils and free-product were observed in an excavation. When all the tanks were removed in March 1994, soil samples collected from the tank excavation pits showed that VOCs, SVOCs, and TPH were present. Benzene was detected at 1,920 μg/L in one water sample taken from an excavation pit. Based on these findings, the site area was recommended for further investigation.

IRP Site No. 9 Area B is adjacent to and immediately west of IRP Site No. 9 Area A and is bounded by Boyington Ave. on the north, Johnson Ave. on the south, and Carey Street on the

DECEMBER 1995

east. The site contained the former diesel fuel dispensing area and had two aboveground tanks on the south side of the site area. Soil staining was reported and may be the result of past spills during fuel transfers. No previous investigation of this site area has occurred. Based on these findings, the site area was recommended for further investigation. The water table is estimated to occur at a depth of approximately 10 to 15 ft bgs. See Subsection 3.2.8 for additional information.

The primary phase will consist of up to twelve points in an initial attempt to delineate the extent of soil and groundwater contamination. Nine of the points will be located in Area 9A and three points will be placed in Area 9B. Two soil samples per primary point will be collected and submitted to the on-site laboratory for analyses. One sample will be collected from the surface to approximately five feet bgs and will be selected based on the highest PID reading, and one sample will be collected from the interval immediately above the water table. One groundwater sample per point will be collected from just below the top of the water table for on-site laboratory analyses. To support the risk screening assessment, two surface soil samples will be collected from the site at intervals of 0 to 6 inches.

The analytical results will be compared to the established project action goals. If contamination is identified above an action goal, up to five secondary points and three primary vertical profile points will then be emplaced. The analyses to be conducted on the samples collected from the secondary points will be for the compounds detected during the primary phase only. Currently, three secondary points and two primary vertical points are designated for the 9A area while two secondary points and one primary vertical point are designated for the 9B area. However, it is possible that based on field results some of the points designated for one area may not be needed and may be moved to other areas where needed. This decision will be made in the field with the concurrence of HAZWRAP and the HQ ANG/CEVR.

Depending on the results of the previous phases, two secondary vertical profile points, for the 9A and 9B areas may be available.

One groundwater sample will be collected from each of the points terminated at the water table. Up to three samples will be collected from the vertical profile points. All samples will be analyzed in the field laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) will be analyzed by the fixed-base laboratory. All soil samples from Site 9 will also be analyzed at the fixed-base laboratory for TPH. IRP Site No. 9 sampling program is presented in Table 6.9.

Four soil locations will also be sampled for soil quality parameters including nitrate, nitrite, ammonia, and phosphorus (total and reactive). Soil gas measurements of oxygen and carbon dioxide will be collected at these locations. Four groundwater locations will be sampled for water quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.

6.3.10 IRP Site No. 10 - Equipment Washrack

IRP Site No. 10 is located at the southeast corner of Bldg 1001 and consists of a 30 ft by 30 ft concrete pad and a drain pipe (Figure 6.12). The concrete pad slopes toward the east to the drain pipe. Effluent from the washrack flows into the drain pipe which empties into a drainage ditch to the northeast of the site area. Information concerning the nature and amount of effluent is unavailable. No formal investigation of IRP Site No. 10 has occurred; however, soil sampling

DECEMBER 1995

was conducted by the Base in 1991 which indicated the presence of oil and grease (7,400 mg/kg) and lead (400 mg/kg) in the site soils. IRP Site No. 10 is recommended for further investigation. The water table is estimated to occur at a depth of approximately 5 to 7 ft bgs. A detailed description of the site background and the sampling results is provided in Subsection 3.2.9 of this document.

The primary phase will consist of up to five points in an initial attempt to delineate the extent of soil and groundwater contamination. Two soil samples per primary point will be collected and submitted to the on-site laboratory for analyses. One sample will be collected from the surface to approximately five feet bgs and will be selected based on the highest PID reading, and one sample will be collected from the interval immediately above the water table. One groundwater sample per point will be collected from just below the top of the water table for on-site laboratory analyses. To support the risk screening assessment, three surface soil samples will be collected from the site at intervals of 0 to 6 inches.

In addition, one surface water and one sediment sample will be collected from the ditch adjacent to the washrack. These samples will be to support the results of the sampling that Base personnel conducted in 1993.

The analytical results will be compared to the established project action goals. If contamination is identified above an action goal, up to four secondary points and three primary vertical profile points will then be emplaced. No secondary vertical profiles are currently proposed.

One groundwater sample will be collected from each of the points terminated at the water table. Up to three samples will be collected from the vertical profile points. All samples will be analyzed in the field laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) will be analyzed by the fixed-base laboratory for VOCs and SVOCs. All soil and sediment samples will be analyzed in the fixed-base laboratory for PPMs and TPH . All groundwater samples will be analyzed by the fixed-base laboratory for PPMs (filtered and unfiltered) and the surface water sample will be analyzed for PPMs (unfiltered only). IRP Site No. 10 sampling program is presented in Table 6.10.

Four soil locations will also be sampled for soil quality parameters including nitrate, nitrite, ammonia, and phosphorus (total and reactive). Soil gas measurements of oxygen and carbon dioxide will be collected at these locations. Four groundwater locations will be sampled for water

quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.

6.3.11 IRP Site No.11 - Washrack West of Building 250

IRP Site No. 11 is located at the southeast corner of Apron A and west of Building 250 (Figure 6.13). The washrack was used to wash planes and consists of a 80 ft by 80 ft concrete pad, a drain pipe, and an oil/water separator. Solvents and degreaser were used to remove undesirable materials from the plane body before applying a soap and water mixture. This site has not been formally investigated; however, one soil sample was collected by a person from the Base during utility installation at the site. A high concentration of TPH was detected (6,000 mg/kg) in the soil sample. IRP Site No. 11 is recommended for further investigation.

142nd FG, Oregon ANG
Portland International Airport
Portland, Oregon

OPTECH
OPERATIONAL TECHNOLOGIES CORPORATION

DECEMBER 1995

The water table is estimated to occur at a depth of approximately 5 to 7 ft bgs. A detailed description of the site background and the sampling results is provided in Subsection 3.2.10 of this document. The primary phase will consist of up to five points in an initial attempt to delineate the extent of soil and groundwater contamination. Two soil samples per primary point will be collected and submitted to the on-site laboratory for analyses. One sample will be collected from the surface to approximately five ft bgs and will be selected based on the highest PID reading, and one sample will be collected from the interval immediately above the water table. One groundwater sample per point will be collected from just below the top of the water table for on-site laboratory analyses. To support the risk screening assessment, two surface soil samples will be collected from the site at intervals of 0 to 6 inches.

The analytical results will be compared to the established project action goals. If contamination is identified above an action goal, up to five secondary points and two primary vertical profile points will then be performed. Depending on the results of the previous phases, two secondary vertical profile points may be available.

One groundwater sample will be collected from each of the points terminated at the water table. Up to three samples will be collected from the vertical profile points. All samples will be analyzed in the field laboratory for VOCs and SVOCs. A selected number of samples (approximately 5%) will be analyzed by the fixed-base laboratory for VOCs and SVOCs. All soil samples will be analyzed in the fixed-base laboratory for PPMs and TPH. All groundwater samples will be analyzed by the fixed-base laboratory for PPMs (filtered and unfiltered). IRP Site No. 11 sampling program is presented in Table 6.11.

Four soil locations will also be sampled for soil quality parameters including nitrate, nitrite, ammonia, and phosphorus (total and reactive). Soil gas measurements of oxygen and carbon dioxide will be collected at these locations. Four groundwater locations will be sampled for water quality parameters including nitrate, nitrite, ammonia, phosphorus (total and reactive), dissolved oxygen, and carbon dioxide.

6.3.12 Total Number of Sampling Locations

Below is Table 6.12 that depicts the number of proposed soil and groundwater locations to be implemented during the RI activities. The number of proposed soil and groundwater samples to be analyzed at the on-site and off-site laboratories are located in Table 1.1 of the QAPP.

SECTION 7.0 FIELD INVESTIGATION PROCEDURES

7.1 INVESTIGATIVE METHODS AND PROCEDURES

7.1.1 Geophysical Surveys

Three types of geophysical surveys will be performed to evaluate the suspected area of the former landfill at IRP Site No. 8. The surveys include horizontal EM, MAG, and GPR. Review of historical aerial photographs and site geology will be performed prior to surveying. The site will be divided into a 30 ft by 30 ft grid. The grid system will be referenced to existing permanent features. The grid system origin and nodes will be marked prior to surveying. The results of the three surveys combined are expected to be effective in identifying any buried material in the area investigated.

An EM survey will be used to identify differences between conductivities of disturbed ground and buried solid waste and that of conductivities in surrounding undisturbed soil. The EM survey will be conducted with measurements recorded at the grid nodes (SOP No.2). A MAG survey will be performed to identify areas of anomalous magnetic field strengths associated with buried metal containers. The survey is proposed to be conducted on a 15 foot spacing on and between the grid to allow sufficient resolution (SOP No. 1). However, grid spacing may be adjusted in the field, depending on the preliminary field test evaluation data. The size and geometry of buried metals containers will be described based on the detector signal intensity during the survey. A GPR survey will be conducted continuously along the grid lines to identify natural sedimentary structures as well as the sharp contacts that occur between disturbed ground and undisturbed ground (SOP No. 3).

7.1.2 Conventional Monitoring Well Installation

Conventional monitoring wells will be installed as background monitoring wells to obtain groundwater samples for the purpose of defining the project contaminant action goals. It is anticipated that a hollow stem auger rig with 8.00- or 6.75-inch ID auger flights will be utilized. Soil samples will be collected continuously from the surface to total depth in a 24-inch split-spoon sampler. The total depth is expected to be approximately 15 ft bgs for the water table wells and 40 ft bgs for the deep wells. Specific details regarding the soil sampling procedures are detailed in a later section. All monitoring wells will be constructed in accordance with current Oregon

Water Resources Department regulations and will be installed by a licensed well driller. Permits required for well construction will be obtained prior to mobilization.

The monitoring wells will be constructed of 2-inch threaded PVC casing and screens. Screen length will be 10 feet for water table wells and should straddle the water table to allow for seasonal fluctuations. The screen length for the deep wells will be 5 ft. Slot size is expected to be 0.010 inches. The optimum placement of the screen for water table wells would have 3 ft of screen above the water table and 7 ft below the water table. Should the water table be at a shallow depth where the minimum Oregon requirements can not be met, a variance will be solicited and acquired prior to completing the well. All risers will be set round, plumb, and true to line. Centralizers will be used as necessary. A well construction diagram will be prepared for each monitoring well. The well construction materials will be decontaminated before installation in the boreholes.

Filter pack will be tremied into the well from 1 foot below the bottom of the screen to 2 feet above the top of the screen. The filter pack will consist of 10-20 size, cleaned, washed and bagged silica sand. Based on previous investigations, the sand pack and screen slot size have been designed such that the screen does not become plugged and aquifer material is not produced into the well annulus. A bentonite slurry seal 2 feet thick will be placed on top of the sand pack. The remaining borehole will be grouted to the ground surface with a cement/bentonite mixture.

HAZWRAP Position Papers 4 (*Filter Pack Size, Slot Size, and Well Screen Size Selection for Monitoring Wells*) and 13 (*Grout Contamination of Groundwater*) will be incorporated into the monitoring well installation program.

Monitoring wells will be completed by finishing the casing approximately 2-1/2 feet above the top of the borehole (short sections of casing may be required) or by flush surface mount. The contractor will contact HAZWRAP and the Base to determine whether a well will be completed with a flush mounting or be completed above ground. For above-grade completion, a 6-inch diameter protective steel riser pipe equipped with a locking cap will be set in the neat concrete grout around the well casing. The well number will be permanently marked on the locking cap. The grout will be built up around the riser pipe in a 3-foot square pad and will be sloped away to aid in runoff. All risers shall be provided with keyed-alike brass or stainless steel locks. The lock keys will be given to the 142nd FG on-site representative.

Three 4-inch diameter steel guard posts filled with cement will be placed around the protective steel riser pipe of monitoring wells. All guard posts will be painted yellow to increase visibility. The bases for the guard posts will be set into concrete and will extend at least 3.5 feet above ground surface. Any well that is to be temporarily removed from service or left incomplete due to delays in construction will be capped with a watertight cap and equipped with a "vandal proof" cover satisfying the ODEQ regulations and recommendations.

Wells completed by flush surface mount will be flush with the land surface. The casing will be cut 2 to 3 inches below land surface and installed with a protective locking lid consisting of a cast-iron valve box assembly. The valve box will be placed in the center of the hole with the top just above the ground surface. A three feet by three feet concrete pad will be placed around the well cover and sloped away from the valve box to divert drainage. The well will also be fitted with a watertight compression casing cap to prevent infiltration of surface water. The well number will be clearly marked on the valve box lid and well casing. All well assemblies will be secured with keyed-alike brass or stainless steel locks. The lock keys will be given to the 142nd FG on-site representative.

7.1.3 Well Development

Well development will not be performed for at least 24 hours after installation and completion to allow sufficient time for the grout to set. The monitoring wells will be developed by submersible pump or surge block (RCRA Groundwater Monitoring, Technical Guidance, 1992) without the use of any type of acids, dispersing agents or explosives. No water or other liquid will be introduced into the well during development other than formation water from that well. Care will be exercised to ensure that the screen is not damaged during development. Water from well development will be placed in drums and segregated by well. Each drum will be clearly labeled depicting at a minimum the well number, the date filled and the name of the Base. The field team will follow specific guidelines presented in SOP No.6 included in Appendix C.

7.1.4 Soil Sampling

Soil samples will be collected utilizing two different methods during the RI. The DPT will be used during the point phase investigations and a conventional hollow stem auger rig will be used to drill the background borings.

Soil samples collected using the hollow-stem auger rig will follow the standard sampling techniques that conform to American Society for Testing Materials (ASTM) D-1586 standards and sampling procedures. Basically soil samples will be collected continuously using a 2-inch diameter split-spoon sampler approximately 24 inches in length. The sampling device is driven ahead of the lead auger flight (via a 140-pound (lb.) hammer dropped 30 inches) into undisturbed soil. Each split-spoon will contain 6-inch long brass sleeves.

Soil samples collected using direct push technology will include driving a 1-inch diameter sampling tube approximately 18 inches in length to a specified sampling depth. At the specified depth the center rod is extracted leaving the sampling tube in place. The sampling tube is driven into the undisturbed soil. Brass liners will also be placed in the sampling tube to collect the sample. Specific guidelines regarding the procedures for DPT are detailed in SOP No.5. Sand retention baskets will be used in sampling tools during soil sampling activities.

Soils will be classified using the Unified Soils Classification System and described according to ASTM D2488-69, "Description of Soils (Visual Manual Procedure)." A minimum of three samples will be collected from the vadose zone in each boring: one sample from the surface (0-1 ft bgs), one sample from the middle of the vadose zone (3-5 ft bgs) and one sample at the bottom of the vadose zone above the water table (6-8 ft bgs). Two samples will be submitted to field laboratory for SVOC and VOC analysis.

An experienced geologist will be present during the operation of the drilling rig for the logging of samples, monitoring of drilling operations, recording of soil and groundwater data, monitoring and recording the well installation procedures, and preparing the boring logs and well construction diagrams.

The on-site geologist will record lithology during drilling of each borehole. This lithologic record will be based on visual inspection of soil samples supplemented by examination of drill cuttings.

The following information will be logged for each boring;

- Boring identification number;
- Name of driller and geologist;
- Method of drilling;
- Bit size, if applicable;
- Sampling method and depth;

- Standard Penetration Test (SPT blows), if applicable;
- PID readings;
- Hole location and elevation;
- Reference elevations for all depth measurements;
- Detailed soil descriptions, including soil moisture/saturation condition;
- Depth at which each distinct stratum is encountered;
- Depth at which groundwater is first encountered while drilling;
- Depth of completed boring or well;
- Location of any fractures, joints, faults, cavities, or weathered zones identified; and
- Signatures of those performing this work.

During all drilling operations, a PID will be used to monitor the breathing zone for organic vapors to determine the need for respiratory protection.

Additionally, a combustible gas indicator will be used during drilling operations to monitor for explosive gases. Special actions will be required if explosive vapors reach 10% of the lower explosive limit (LEL). These actions are described in the site Health and Safety Plan (Appendix A).

7.1.5 Groundwater Point Installation

Groundwater samples will be collected using DPT and employing one of the three well point configurations detailed in SOP No. 5. The initial configuration to be employed is the mill-slotted well point. It is possible that the field team will start with this method and recommend changing to a different method. This will not be done without agreement from HAZWRAP and the HQ ANG/CEVR.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 8.0 SAMPLE COLLECTION PROCEDURES

8.1 SEDIMENT/SURFACE SOIL SAMPLING

Sediment samples will be collected with a stainless steel scoop and will be placed in glass jars. Surface soil samples will be collected from 0-1 foot depths using a stainless steel long-handled corer with a brass liner or split-spoon sampler with brass liner. The liner will be removed and the ends of the liner sealed Teflon™ barrier, a square piece of aluminum foil, and Teflon™ or plastic endcaps. The sample tubes and jars will be labeled and placed into a zip-top bag and immediately placed into a cooler containing ice for delivery to the laboratory. VOC samples will be collected first to prevent vaporization of any volatile analytes.

If there is insufficient recovery to meet the minimum sample volume for analysis, then additional samples will be collected within one-foot of the initial sampling location. The corer will be forced to a depth of no more than one foot and removed in a smooth twisting motion. The sample will be extruded into a decontaminated stainless steel pan. The sample volume will be homogenized and individual sample bottles filled using the homogenized mixture. Samples will be sealed, labeled and placed into an ice-filled cooler for transportation to the laboratory.

8.2 SUBSURFACE SOIL SAMPLING

Subsurface soil samples will be obtained from test borings by a California-style or similar sampler DPT with Teflon™ liners and/or brass tubes. Liners will be placed inside the split-spoon samplers to minimize the loss of VOCs through volatilization. Two samples will be collected, one from the intervals 3-5 ft and 6-8 ft . The 6-8 ft sample will be adjusted in the field to correspond to the unsaturated soil zone immediately above the watertable. All samples will be screened using a PID and analyzed on site using a field GC/MS. Samples will also be submitted to the fixed-base laboratory for VOC (5%), SVOC (5%), PCB (100%), TPH (100%), and PPM (100%), depending on the site specific DQOs.

8.3 GROUNDWATER SAMPLING

Groundwater samples will be collected from all DPT groundwater grab sampling points, existing monitoring wells, and newly installed monitoring wells. Samples will be screened in the field for VOC and SVOC constituents. Additional volumes will be collected for fixed-base laboratory analysis. This data will be used to determine if groundwater contamination is present and, if

present, to aid in defining the horizontal and vertical extent of groundwater contamination and background groundwater conditions. Filtered and unfiltered groundwater samples for metal analysis will be collected for the fixed-base laboratory. Monitoring well sampling will not take place until well construction and development has been completed. Before the well is purged and sampled, well headspace will be checked for organic vapors using a PID. The water level in the well will then be measured with a water level indicator and recorded in the field logbook. If available, the elevation of the surveyed measuring point will also be recorded.

If product is detected within a well, its thickness will be determined using an oil/water interface probe, or a clear bailer. After the water level and product measurements have been made, a low flow pump (RCRA Groundwater Monitoring, Technical Guidance, 1992) will be used for purging and sampling, if allowed by USEPA Region X and the ODEQ. If product is detected, the well will not be purged or sampled. Field measurements of pH, turbidity, conductivity, and temperature will be measured to ensure that each well has stabilized. Wells will be purged until they have stabilized or a total of three to five well volumes have been recovered. In wells with slow recovery/recharge, VOC samples will be collected when sufficient volume of liquid has recovered in the well. All other samples will be collected based on the site specific sampling program.

8.4 SURFACE WATER

Surface water samples will be collected from the Main Drainage Ditch at IRP Site No. 4. All water samples will be collected directly into sample bottles. Samples will be collected from the downstream section first, depending on the visual inspection of the drainage pit prior to sampling. The sample will be collected with as little disturbance of underlying sediments as possible. Samples will be collected for VOC and SVOC analysis for the on-site laboratory, and for VOC, SVOC, PPM (unfiltered), and PCB for the fixed-base laboratory. Samples will immediately be sealed, labeled and placed into an ice-filled cooler for transportation to the laboratory.

8.5 LAND SURVEY

Newly installed monitoring wells and sampling locations will be surveyed by a state-licensed surveyor to define their locations and elevations for future reference. Proposed soil sampling locations will be marked and surveyed prior to beginning soil sampling. All wells and borings shall be referenced both horizontally and vertically. The top of the well casing will be surveyed off a permanent marker (e.g., manhole cover, fire hydrant, bridge abutment, etc.), and shot to

the nearest 0.01 foot. A permanent benchmark will be established near each site, and tied to Geodetic Vertical Datum of 1929. All positions and coordinates of all permanent points within the control traverse shall be shown. Boreholes will be located within ± 0.1 foot horizontally and ± 0.01 foot vertically.

8.6 FIELD QUALITY CONTROL

Field measurement parameters will include PID readings, temperature, pH, turbidity, conductivity, dissolved oxygen, carbon dioxide, water level, and field GC/MS results. The temperature of the water will be measured using an electronic digital thermometer. This measurement will also be used to calibrate the pH and conductivity meter. The pH of the water will be measured using a portable pH meter. The meter will be calibrated daily using traceable buffer solutions of the appropriate range for expected pH values. The meter will also be recalibrated periodically during periods of continued use as recommended by the manufacturer. The specific conductance of the water will be measured with a portable specific conductance meter. A standard potassium chloride solution will be used to calibrate the instrument daily. The meter will also be recalibrated periodically during periods of continued use as recommended by the manufacturer. Turbidity refers to the solids and organic matter that do not settle out of water. A light scattering turbidity measurement equipment will be used which will measure turbidity in nephelometric turbidity units (NTUs). The PID will be calibrated daily with 100 parts per million (ppm) isobutylene, following manufacturers recommendations. Field measurement instrument calibration procedures are discussed in detail in Appendix B (QAPP), Section 8.0. The water level measuring device will be visually inspected of tears, bends or any damage that could effect the measure. Field GC/MS instruments will be calibrated according to the CLP methods referenced in the QAPP. Field GC/MS CLP VOC and SVOC analyses, however, will require a 3-point calibration.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 9.0 SUMMARY OF POTENTIAL ARARs

The investigation is being conducted pursuant to CERCLA and in conformance with the requirements of the NCP. Section 121 of CERCLA requires remedial actions to comply with all ARARs under federal and state environmental laws. Applicable requirements are substantive environmental protection requirements specifically addressing a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance at a site. Relevant and appropriate requirements are those which, while not applicable, are sufficiently similar to circumstances encountered at a site that their use is well suited.

There are three types of ARARs:

- Location-specific ARARs are restrictions imposed on activities or concentrations of hazardous substances solely because they occur in special locations.

- Chemical-specific ARARs are health- or risk-based criteria which establish the acceptable amount or concentration of a chemical that may be found in or discharged to the ambient environment;

- Action-specific ARARs set controls or restrictions on design and performance aspects of activities at the site.

Activities conducted during the Remedial Investigation/Feasibility Study (RI/FS) process must comply with ARARs to the extent practicable (55 Fed. Reg. 8756, Mar. 8, 1990).

ARARs are progressively identified and applied on a site specific basis as the RI/FS proceeds. The initial step in the process entails the survey of potential ARARs for the remedial process at the subject site. The next step in the ARARs process is the comparison of statutory and regulatory requirements with site-specific factors to evaluate whether a site is currently in compliance.

Suspected sources of contamination, historical site usage, and the known or potential effects of contaminants on the environment help identify potential federal, state, and local ARARs. The application of ARARs to the RI process is dependent upon results of the field investigation. Confirmation of contamination at a site, identification of the specific contaminant(s), and subsequent laboratory analysis and quantification determine the application of chemical specific

ARARs. Additional action- and location-specific ARARs are determined when potential remediation alternatives are considered.

The degree to which site-specific factors are incorporated into the ARARs development process varies considerably. In the case of hazardous chemicals, evaluation of site-specific factors is an integral part of the ARARs process even when prerequisites based on statutory or regulatory requirements exist. Action- and location-specific ARARs are determined when any required remediation options are being considered. Groundwater ARARs are considered to be pertinent because some chemicals of potential concern in soils may impact groundwater.

The following Section provides a preliminary summary of key ARARs that may be relevant to RI activities at the Base.

9.1 RESOURCE CONSERVATION AND RECOVERY ACT (RCRA)

Federal RCRA regulations governing hazardous waste management provide potential ARARs for IRP activities at the Base. RCRA regulations are applicable chemical-specific ARARs if waste is listed in 40 CFR 261 or exhibits RCRA characteristics, and may be relevant and appropriate if otherwise. RCRA may also impose location- and action-specific ARARs. USEPA's investigation-derived waste (IDW) policy discusses options for managing materials, such as drill cuttings and purge water, which are generated during RI activities.

Waste Identification. Materials excavated or removed from the site (e.g., drill cuttings, contaminated soil, and contaminated groundwater) will be regulated as hazardous waste if they meet the federal definition provided in 40 CFR 261.

Waste Generation and Transport. RI activities or remedial alternatives involving the movement or removal of hazardous waste trigger RCRA hazardous waste generator requirements provided in 40 CFR 262. When hazardous waste is shipped off-site in regulated amounts, the manifesting and transport procedures in 40 CFR 263 must be followed. As applicable, the Base will sign all hazardous waste manifests as the generator of the waste.

Land Disposal Restrictions. RCRA regulations in 40 CFR 268 set forth Land Disposal Restrictions for RCRA wastes. These restrictions were required by the Hazardous and Solid Waste Amendments (HSWA) of 1984 to prohibit the continued land disposal of hazardous wastes beyond specified dates. However, wastes treated in accordance with treatment standards provided

in 40 CFR 268 Subpart D may be land-disposed as provided therein. The Land Disposal Restrictions potentially affect the disposal of hazardous wastes generated during the RI or subsequent remedial activities and may be considered both action- and chemical- specific ARARs.

Treatment, Storage, and Disposal Facilities (TSD). If remedial alternatives for the site involve the construction or use of RCRA TSD facilities, regulations provided in 40 CFR 264 become action-specific ARARs. Various subsections of 40 CFR 264 provide standards and procedures for the operation of hazardous waste TSD facilities. For example, a common disposal practice is to create a waste pile of contaminated soil as part of the remediation process. 40 CFR 264, Subpart L promulgates Federal standards for waste piles, including their design, operating requirements, monitoring and inspection, closure, and post-closure care. Other subparts control tank systems, surface impoundments, land treatment units, landfills, incinerators, and miscellaneous TSD units.

9.2 SAFE DRINKING WATER ACT (SDWA)

Federal regulations promulgated pursuant to the SDWA govern the quality of, usage of, and discharge to groundwater. Maximum Contaminant Levels (MCLs) specified in 40 CFR 141.11 - 141.16 are legally enforceable federal drinking water standards established by USEPA Maximum Contaminant Level Goals (MCLGs) specified in 40 CFR 141.50-141.51 are nonenforceable, health-based goals for drinking water. MCLGs are set at levels at which no adverse health effects may arise. MCLs are set as close as practical to MCLGs. The Primary Federal Drinking Water Standards and the Oregon Numerical Groundwater Quality Standards for Volatile and Semi-Volatile Organic, and Inorganic Constituents are presented in Table 9.1. As stated by the USEPA, state drinking water standards must be no less stringent than ones established by the USEPA. Consequently, the State of Oregon enforces their Groundwater Quality Standards or USEPA MCLs dependent upon which is the most stringent. These potential ARARs may be used to identify a range of target clean-up levels for groundwater at the Base.

9.3 CLEAN WATER ACT (CWA)

The Federal CWA and pursuant regulations provide potential location-, chemical-, and action-specific ARARs for IRP activities at the Base. Since surface water bodies are located both on-site and downgradient of the sites, federal, state, and/or local surface water ARARs will apply.

[b] Total Trihalomethanes

Ambient Water Quality Criteria (AWQC). The USEPA has promulgated AWQC for surface water through 40 CFR 131. Candidate remedial actions involving contaminated surface water or groundwater must be evaluated within the context of follow-on water usage and the circumstances or the actual or potential release before implementation. As a general statement, AWQC are applied when evaluating clean-up levels.

National Pollutant Discharge Elimination System (NPDES). The OANG is a co-permittee in an NPDES permit with the Portland International Airport. Permit requirements and conditions provide action- and chemical-specific ARARs.

9.4 OCCUPATIONAL SAFETY AND HEALTH ACT (OSHA)

Although not strictly ARARs, as required by the NCP at 40 CFR 300.150, all site operations are governed by OSHA Standards of Health and Safety under 29 CFR 1910.120, Hazardous Waste and Emergency Response. The health and safety officer for the RI field investigation will ensure all site workers meet the requirements of the health and safety plan, maintain appropriate training, possess and use all PPE, and take all precautions to eliminate exposure to unsafe or unhealthy situations. Other applicable OSHA requirements include health and safety for construction (29 CFR 1926), general industry (29 CFR 1910), and recordkeeping and reporting (29 CFR 1904).

9.5 HAZARDOUS MATERIALS TRANSPORTATION ACT (HMTA)

If material containing hazardous wastes is to be transported off-site, U.S. Department of Transportation (DOT) hazardous material transportation requirements in 49 CFR 171-179, pursuant to the federal HMTA, may be action-specific ARARs for RI activities. These requirements are supplemental to RCRA transporter requirements in 40 CFR 263. Stored hazardous materials will be containerized and labeled in accordance with requirements.

9.6 CLEAN AIR ACT (CAA)

The Federal Clean Air Act may provide action and chemical specific ARARs for IRP activities, including field investigations and subsequent remedial actions, including soil excavation or incineration. All remediation activities must comply with National Primary and Secondary Ambient Air Quality Standards (NAAQS) found in 40 CFR 50. Rules governing particulate matter less than 10 microns in size (PM_{10}), which can have potential detrimental effects on the lungs, are contained in 40 CFR 50. All field activities involving air emissions must ensure compliance with the PM_{10} standard.

9.7 FEDERAL GUIDANCE TO BE CONSIDERED (TBC)

In addition to federal and state requirements that may be applicable or relevant and appropriate to IRP activities, federal non-regulatory criteria should be considered. These chemical specific TBCs, used to help characterize risks and to set clean-up goals, include the following:

- USEPA Risk Reference Doses;
- USEPA Health Advisories;
- USEPA Carcinogen Assessment Group Potency Factors;
- USEPA Acceptable Intake Values, Chronic and Subchronic; and
- USEPA Guidance Manual on Water-related Fate of 129 Priority Pollutants.

9.8 STATE REQUIREMENTS

In addition to federal ARARs, several State of Oregon regulations may be applicable or relevant and appropriate to RI activities and potential remedial alternatives at the OANG.

Oregon Air Pollution Control Standards. The Oregon Department of Environmental Quality (ODEQ) regulates all general and specific air emissions by setting standards and regulations controlling air contaminant emissions so as to maintain air quality at the highest possible levels and to maintain contaminants at the lowest possible levels. These regulations could provide relevant and appropriate requirements for any remedial activities at the 142nd FG site.

Oregon Hazardous Waste Management Regulations. Rules and criteria for the identification, storage, treatment, transportation, and disposal of hazardous wastes are established in these regulations. These regulations provide potential ARARs for RI activities involving the movement or removal of hazardous wastes.

Oregon Groundwater Quality Protection Regulations. Standards have been written to supplement federal water quality requirements and may be considered potential action or chemical specific ARARs for the RI or planned remedial actions. The ODEQ regulates all public water supplies in the state and has established MCLs which may be used as cleanup levels for remedial activities. Table 9.1 includes Oregon Groundwater Reference and Guidance Levels which are contaminant concentration level used to evaluate the significance of a particular contaminant in groundwater. Reference Levels generally indicate when groundwater may not be suitable for human consumption. Guidance Levels generally indicate when groundwater may not be suitable for use as drinking water due to its aesthetic characteristics.

Oregon State-Wide Water Quality Management Plan. These rules describe Oregon's plans for the management of the quality of public waters within the State of Oregon. The ODEQ evaluates each discharge and activity on a case-by-case basis. Since surface water bodies are located both

on-site and downgradient of the sites, these regulations provide potential ARARs for RI activities and subsequent remedial actions.

Oregon Oil and Hazardous Material Spills and Releases. The ODEQ uses these regulations to specify the reporting requirements, cleanup standards, and liability attached to a spill or release or threatened spill or release involving oil or hazardous material. These regulations provide potential ARARs for RI activities and subsequent remedial actions.

Oregon Hazardous Substance Remedial Action Rules. These regulations establish the standards and process to be used for the determination of removal, remedial action, and degree of cleanup required in the event of a release or threat of a release of a hazardous substance. These regulations provide potential ARARs for RI activities and subsequent remedial actions. Table 9.2 includes Oregon Soil Cleanup Standards for specific contaminants, including Residential and Industrial Maximum Allowable Soil Concentrations and Optional Soil Cleanup Levels, each for application in specific situations. These numbers will be considered for setting soil cleanup levels in future remediation activities.

Oregon Underground Storage Tank Rules. These regulations impose requirements for release detection notification and reporting, corrective actions, closures, and other subjects of USTs. If during the course of the investigation a UST is found to be leaking, these ARARs will become action-specific standards. Table 9.3 presents numeric soil clenup standards for TPH. The matrix cleanup levels are determined by assigning a score to five site-specific parameters:

- Depth to groundwater
- Mean annual precipitation
- Native soil or rock type
- Sensitivity of uppermost aquifer
- Potential receptors

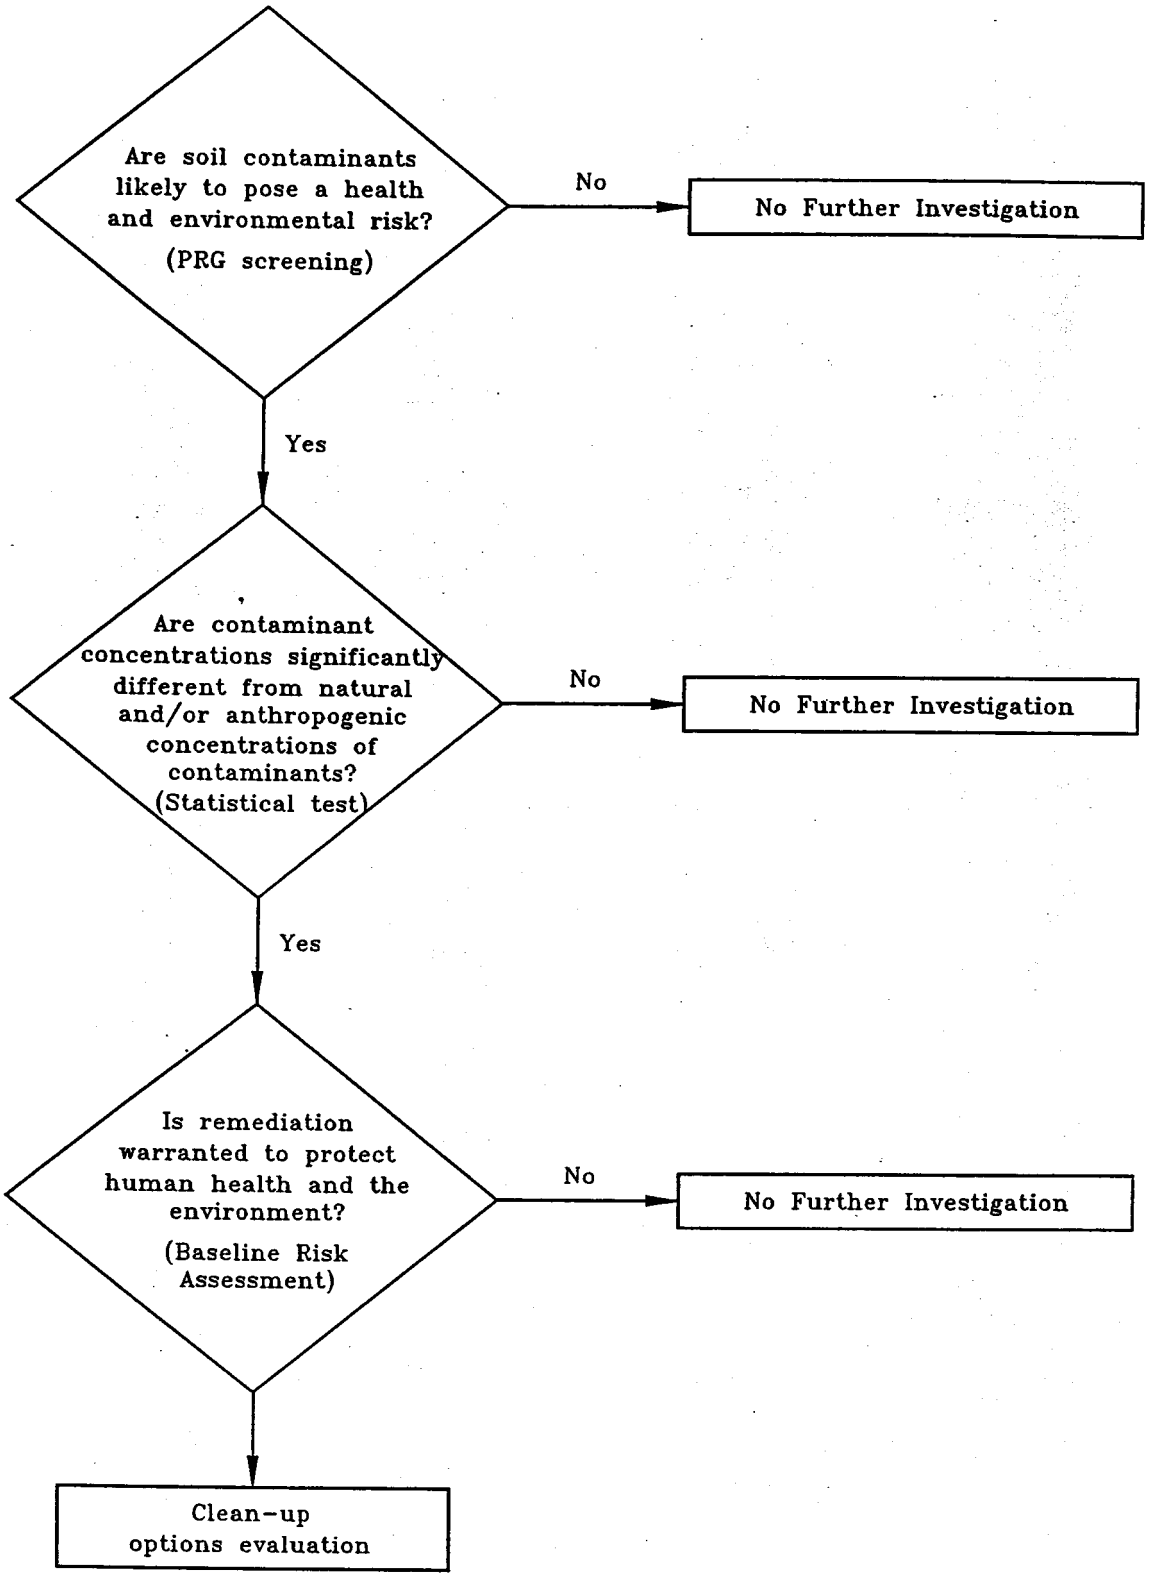
9.9 LOCATION-SPECIFIC ARARs

No location-specific ARARs have yet been identified at this site. New information discovered during the field investigation and subsequent laboratory analyses may broaden the initial set of project ARARs.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 10.0 SCREENING RISK ASSESSMENT

10.1 DEVELOPMENT OF THE CONCEPTUAL SITE MODEL



Chemical and physical properties that affect the transport of identified contaminants at each site will be evaluated with respect to the geologic and hydrogeologic conditions that effect contaminant migration. In addition, possible degradation products of detected contaminants will also be evaluated as they relate to future exposure. As a part of this analysis, a site conceptual model for each site will be constructed to evaluate, illustrate, and document potential routes of migration and possible receptors. The conceptual site model will serve as the basis for defining the scope of the risk-based screening process.

10.2 HUMAN HEALTH SCREENING RISK ASSESSMENT

10.2.1 The Screening Process

Screening generally refers to a process of using conservative assumptions about contaminant concentration and exposure to rapidly identify two distinct groups of contaminants: contaminants that definitely pose no health or ecological risk, and contaminants that may warrant a detailed more site-specific analysis to establish whether concern is warranted. Screening is useful because it rapidly and definitively focuses risk issues to only those contaminants and exposure routes that may pose a potential problem, allowing for a less expensive and more targeted baseline risk assessment (BRA) effort. At many sites the screening illustrates that no further risk assessment is required because all the contaminants are removed from concern. In other cases BRAs can focus on a small group of contaminants in a limited number of contaminated media and exposure routes, dramatically reducing the effort needed to conduct the BRA, thus simplifying decisions about remediation.

In the screening process for these sites, a three-phased approach is recommended to conduct the screening. Figure 10.1 outlines the screening process that consists of a comparison of contaminant concentrations to RBCs and, if needed, a comparison to background, and a BRA. This work plan addresses the first phase of the screening process (comparison to RBCs). The primary exposure pathways for each site will be screened, based on the exposure pathways identified by the conceptual site models. Primary exposure pathways will be defined as those exposure routes that, in the professional experience of the risk assessor, are likely to dominate

OCTOBER 1995

the risk for a given receptor and contaminated medium. Because USEPA Region X has used USEPA Region III methods in the past for site screening and RBC development, this screening assessment will use the most recent revision of the USEPA Region III method for applying RBCs for site screening described in "Selecting Exposure Routes and Contaminants of Concern by Risk-Based Screening" (EPA/903/R-93-001). These RBCs are established at risk levels of 1×10^{-6} and hazard quotient of 1 for residential exposures and all acceptable data will be screened against the appropriate Region III RBCs.

The RBC methodology, while described in detail in the referenced document (Appendix E), involves the use of the maximum concentration of each substance detected in each medium at each site. If the maximum concentration exceeds the RBC for that medium, the contaminant is retained for inclusion in the background comparison screening. This second phase of screening, consists of a comparison of site samples with upgradient background samples. If, after screening against background, Contaminants of Potential Concern (COPCs) remain, the third phase of screening, consisting of a BRA, will need to be performed. A BRA will establish which COPCs are actually contaminants of concern posing significant risk to receptors. Noting that in this screening framework COPCs do not necessarily warrant remedial action at the site is important. However, COPCs do warrant further evaluation in a BRA. Only the BRA (to be conducted in Phase III) identifies which contaminants warrant remediation. Ultimately, contaminants that do not exceed an RBC or background concentration are dropped from consideration in the contaminated medium in question. If a specific contaminant does not exceed its RBC or background concentration in any medium, the contaminant is dropped from further consideration. If no contaminant in a specific medium exceeds its RBC or background concentration, the medium is dropped from future risk assessment activities.

The results of the contaminant screening will be presented by site. If no contaminants in any media exceed the RBCs, the media at the site may be recommended for no further action. If no media at any site exceeds the RBCs, then the entire site may be recommended for no further action. Contaminants that exceed the RBCs will be recommended for a Phase II screening against background. Should this second screening identify COPCs, a focused risk assessment will be designed to evaluate those contaminated media and pathways of potential concern defined by the screening.

10.2.2 Characterizing the Ecological Setting

The ecological risk assessment should provide information on potential threats to plants and animals (other than humans and domesticated species as addressed in the previous section) associated with contaminants or with actions designed to remediate a site. Since most of the site addressed by this investigation are primarily in industrial areas with little wildlife, few if any of the sites are expected to require an extensive environmental evaluation. However, a preliminary ecological reconnaissance will be performed at the Base to identify the potential presence of any threatened and/or endangered species, or sensitive habitat that may support them. The site and directly adjacent areas will also be evaluated to determine if there are any potentially protected areas, or if any possible contamination identified on any site could potentially migrate to a protected area. It is possible that the greatest source of risk to ecological receptors from site contaminants exists off the site at the ultimate discharge to the Columbia Slough.

The following information will be obtained for each site:

- Information describing the common flora and fauna;
- Presence and location of any threatened, endangered, or rare species, and if present, presence and location of potential supporting critical habitats; and
- Presence or location of any sensitive environmental areas.

Based on this information, Ecological Site Conceptual Models will be developed.

10.3 ECOLOGICAL RISK COMPARISONS

Data appropriate for the receptors identified in the ecological reconnaissance will be screened against appropriate ecological benchmark values. Possible sources for the benchmark comparison values include USEPA, ODEQ, State Departments of Natural Resources and Conservation, Oak Ridge National Laboratory, foreign government sources (Canada), and the open literature. The final selection of benchmarks will depend on the identification of receptors and exposure pathways.

Data from sites with common characteristics such as grassy areas, wooded areas, and drainage areas will be combined for all the sites and compared with the appropriate terrestrial, sediment or surface water benchmark. The results of the bench mark screening will be presented with the results of the human health risk-based screening. If contaminant levels exceed benchmarks and potential receptors have been identified, further ecological risk assessment may be warranted.

SECTION 11.0 EQUIPMENT DECONTAMINATION PROCEDURES

Decontamination of drilling and sampling equipment is necessary to minimize the possible spread of contamination to clean zones, to reduce exposure to personnel, and to reduce the possibility of cross-contamination of samples when equipment is to be used more than once during a sampling event. To verify the thoroughness of the decontamination procedures, rinseate samples (equipment blank) will be collected and analyzed, as required, from the decontaminated sampling equipment. The procedures and frequency of these samples are described in the project QAPP included as Appendix B.

11.1 HEAVY EQUIPMENT

Heavy equipment (i.e., drill rig, augers, and DPT) will be decontaminated at a washrack designated appropriate by the Base and selected on the basis of accessibility to heavy equipment, including the drilling rig, DPT, and downhole equipment. The decontamination procedures will follow the SOP No. 4 presented in Appendix C.

11.2 SAMPLING EQUIPMENT

Sampling equipment (i.e., split spoons, spatulas, stainless steel bowls) will be decontaminated at or near the area chosen for heavy equipment decontamination, or at an area established on-site away from the suspected area(s) of contamination. At each site, the sampling equipment will not be allowed to come into contact with the ground or any potentially contaminated surface. Decontamination procedures will follow the SOP No. 7 presented in Appendix C.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 12.0 BOREHOLE ABANDONMENT PROCEDURES

Once the drilling and soil sampling operations have been completed the borings will be grouted. All borings will be backfilled with cement grout using a tremie pipe. The cement grout will consist of a mixture of Portland cement, (ASTM C-150), and water in the proportion of not more than seven gallons of potable water per bag of cement (one cubic foot or 94 pounds). Additionally, a 3% by weight volume of bentonite powder will be added to the mixture. All borings will be backfilled with grout immediately after the sampling has been accomplished to prevent downward migration of contaminants through the open borehole. In order to prevent accidents, all borings will be clearly marked or guarded at all times until backfilled.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 13.0 INVESTIGATIVE DERIVED WASTE (IDW) MANAGEMENT

During field investigation activities, several different types of solid and liquid wastes may be generated including drill cuttings, well purging waters, decontamination fluids, and other drilling incidentals. The ultimate disposal of these wastes depends on the degree of environmental contamination present at the site and the likelihood that these wastes would be similarly contaminated. Custody of all drummed material, including soil cuttings, well development and purge waters, and decontamination fluids will be turned over to OANG personnel at the end of the field effort, who will be responsible for their final disposition. The following outlines a strategy for the disposal of these wastes. Analytical results and appropriate decontamination will be provided to the Base to assist in their disposition of IDW that is designated for off-site treatment, storage, and disposal (TSD).

13.1 SOIL CUTTINGS

A minimal amount of drill cuttings are expected to be generated during field activities at the ten sites due to the proposed direct push technique. However, the background wells will be installed using a conventional drill rig and are expected to generate a more significant amount of drill cuttings. Because drilling will only occur at background locations, we anticipate encountering clean soils. Therefore, all soil cuttings derived during drilling operations will be initially placed on plastic next to the borehole and covered. If field laboratory results from soils analyses indicates the cuttings are below USEPA Region III Industrial RBCs, they will be spread at the surface near the borehole location. If field laboratory results from soils analyses indicates the cuttings exceed Region IX PRGs, they will be drummed and sampled for TCLP characteristics. If the TCLP analysis indicates the soil is classified as a hazardous waste, it will be disposed of as such. If the TCLP analysis indicates the soil is not a hazardous waste, it will be disposed of in a controlled Sanitary Landfill. Figure 13.1 is a decision tree diagram that illustrates this approach.

Upon completion of the drilling activities, any containerized drill cuttings will be transported to an on-base staging area designated by OANG personnel. Residual sample material from the field screening laboratory will be containerized near the field office screening area and transported to the staging area until the laboratory analysis is completed. OANG personnel shall be responsible for the final disposition of all containerized drill cuttings.

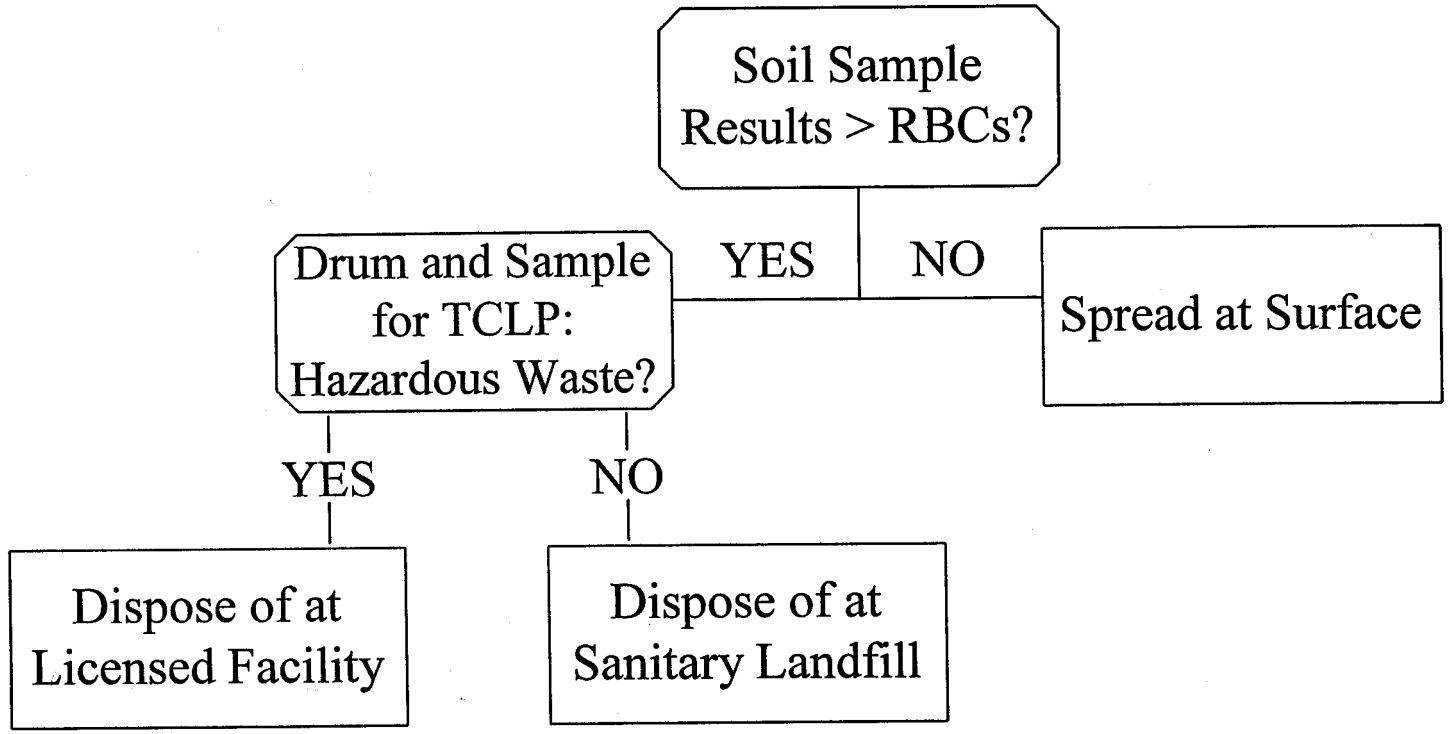

Figure 13.1

Soil IDW Disposal Decision Diagram
142nd Fighter Group, Oregon Air National Guard
Portland International Airport, Portland, Oregon

OPTECH
Operational Technologies
CORPORATION

13.2 WELL DEVELOPMENT AND PURGE WATERS

Well development and purge waters will be containerized at each site in poly tanks or drums. Representative samples will be screened for VOCs and SVOCs with the field GC/MS. If results are within permit requirements, the fluids will be discharged to the sanitary sewer. If results exceed permit requirements, the fluid will be sampled for TCLP characteristics. Analytical results indicating the fluid is a Hazardous Waste will result in drumming and disposal at a licensed facility. Analytical results indicating the fluid is not a Hazardous Waste will result in drumming and disposal at a sanitary landfill. All fluids are expected to be disposed of at the Base waste water treatment plant via the sanitary sewer. OANG personnel shall be responsible for the final disposition of all containerized fluids. Analytical results and appropriate decontamination will be provided to the Base to assist in their disposition of IDW that is designated for off-site transportation. Figure 13.2 presents a decision tree that illustrates this process.

13.3 DECONTAMINATION FLUIDS

Heavy equipment such as drilling equipment and augers, will be decontaminated at a designated area located by the Base contact. The decontamination process and construction of the pad will follow SOP No. 4.

Water generated from the decontamination of the sampling equipment will be containerized on-site in poly tanks or drums. The waters will not be segregated by site since the differences in chemical composition are expected to be minimal between sites. The decontamination fluids will be sampled and handled like well development fluids. Figure 13.2 illustrates the decision tree process for determining proper disposal .

13.4 DRILLING INCIDENTALS

Discarded personal protective equipment, plastic, aluminum foil, and other drilling incidentals will be placed in plastic garbage bags and disposed of in a sanitary landfill.

SECTION 14.0 PROJECT SCHEDULE AND DELIVERABLES

14.1 PROJECT SCHEDULE

The project schedule presented in Figure 14.1 outlines benchmark events for accomplishing preparation of the RI WP. Schedule status will be updated as necessary to reflect any significant changes to the project tasks as they are completed. Updated schedules will be submitted to HAZWRAP and the Base PMs, with any deviations noted and explained. Monthly progress reports will be submitted to the HAZWRAP PM only. Significant events which may occur and affect the schedule will be reported out-of-cycle where necessary, if deemed appropriate to insure efficient project implementation.

14.2 MEETINGS

The project contractor will attend a project kickoff meeting at the Base prior to the start of field activities and up to three project progress meetings during the field effort to discuss project findings and recommendations. These meetings will be attended by the project contractor, Project Manager, HAZWRAP representative, and the Base Project Manager. Within one week of meeting completion, five copies of draft summary minutes will be submitted to HAZWRAP and the Base PMs for review and approval. The minutes will include a summary of key issues discussed and their disposition, a list of meeting attendees with address and telephone numbers, and any other pertinent information discussed at the meeting. Upon approval, copies of the minutes will be submitted to persons included on a distribution list compiled from the meeting attendee list. Minutes will not be distributed to individuals or organizations whose names do not appear on the distribution list without prior authorization from HAZWRAP and the HQ ANG/CEVR.

14.3 PROJECT DELIVERABLES

14.3.1 Field Technical Memorandum

Throughout the duration of field activities, a technical memorandum will be submitted to the HAZWRAP and the Base PMs upon completion of each laboratory Sample Data Package. This progress update will include the Sample Data Package, a compilation of the analytical results, an

isoconcentration map of the sample results included in the data package, and a discussion of any problems encountered as well as a proposed solution. Technical memoranda, preliminary reports, field documentation, unvalidated analytical data and reports, etc., will be marked with the following statement: "This data has not been finalized and is not intended for distribution or final interpretation. Only data presented in the final RI report should be considered as final data. Interim data will be used for interpretive purposes and will only be available for use by approved personnel."

14.3.2 Monthly Progress Reports

A monthly letter report summarizing contract progress to date will be submitted to the HAZWRAP PM. The report will be a management summary and will address any problems encountered in completing project tasks, as well as any changes in scope or direction of the project. The report will be formatted on a work breakdown structure basis to show the actual effort expended versus the scheduled levels of effort, the remaining duration, and the planned and accrued costs.

The letter report will be accompanied by a Contract Management Summary Work Sheet which will include: activity start date if the activity started during the reporting month; the activity finish date if the activity was finished during the reporting month; and the remaining days to complete any ongoing activities. The monthly progress report shall be submitted to the HAZWRAP PM no later than the eighth working day of each month for the duration of the Task Order.

14.3.3 Remedial Investigation Report

14.3.3.1 Remedial Investigation Report Purpose

The RI Report will document the investigative strategy and rationale, the field and analytical data collected, the risk assessment findings, and the conclusions and recommendations for each of the ten sites addressed by the RI. The report will provide documentation to quantify the horizontal and vertical magnitude and extent of contamination and describe the migration of any contaminants from the sites which may exist. In addition, it will address the possible risk to human health and the environment from any contaminants of concern and support informed decisions on possible remedial technologies which may be proposed for any of the ten sites.

14.3.3.2 Remedial Investigation Report Format

Table 14.1 outlines the RI Report format proposed for the ten IRP Sites at the OANG.

14.3.4 Decision Documents

If results from the RI investigation indicate a recommendation of NFA for the medium and/or site(s) of concern, a DD will be prepared in accordance with CERCLA, Superfund Amendments and Reauthorization Act (SARA), and the NCP. The DD shall, at a minimum, contain a brief summary of site conditions with detailed rationale to support the NFA recommendation.

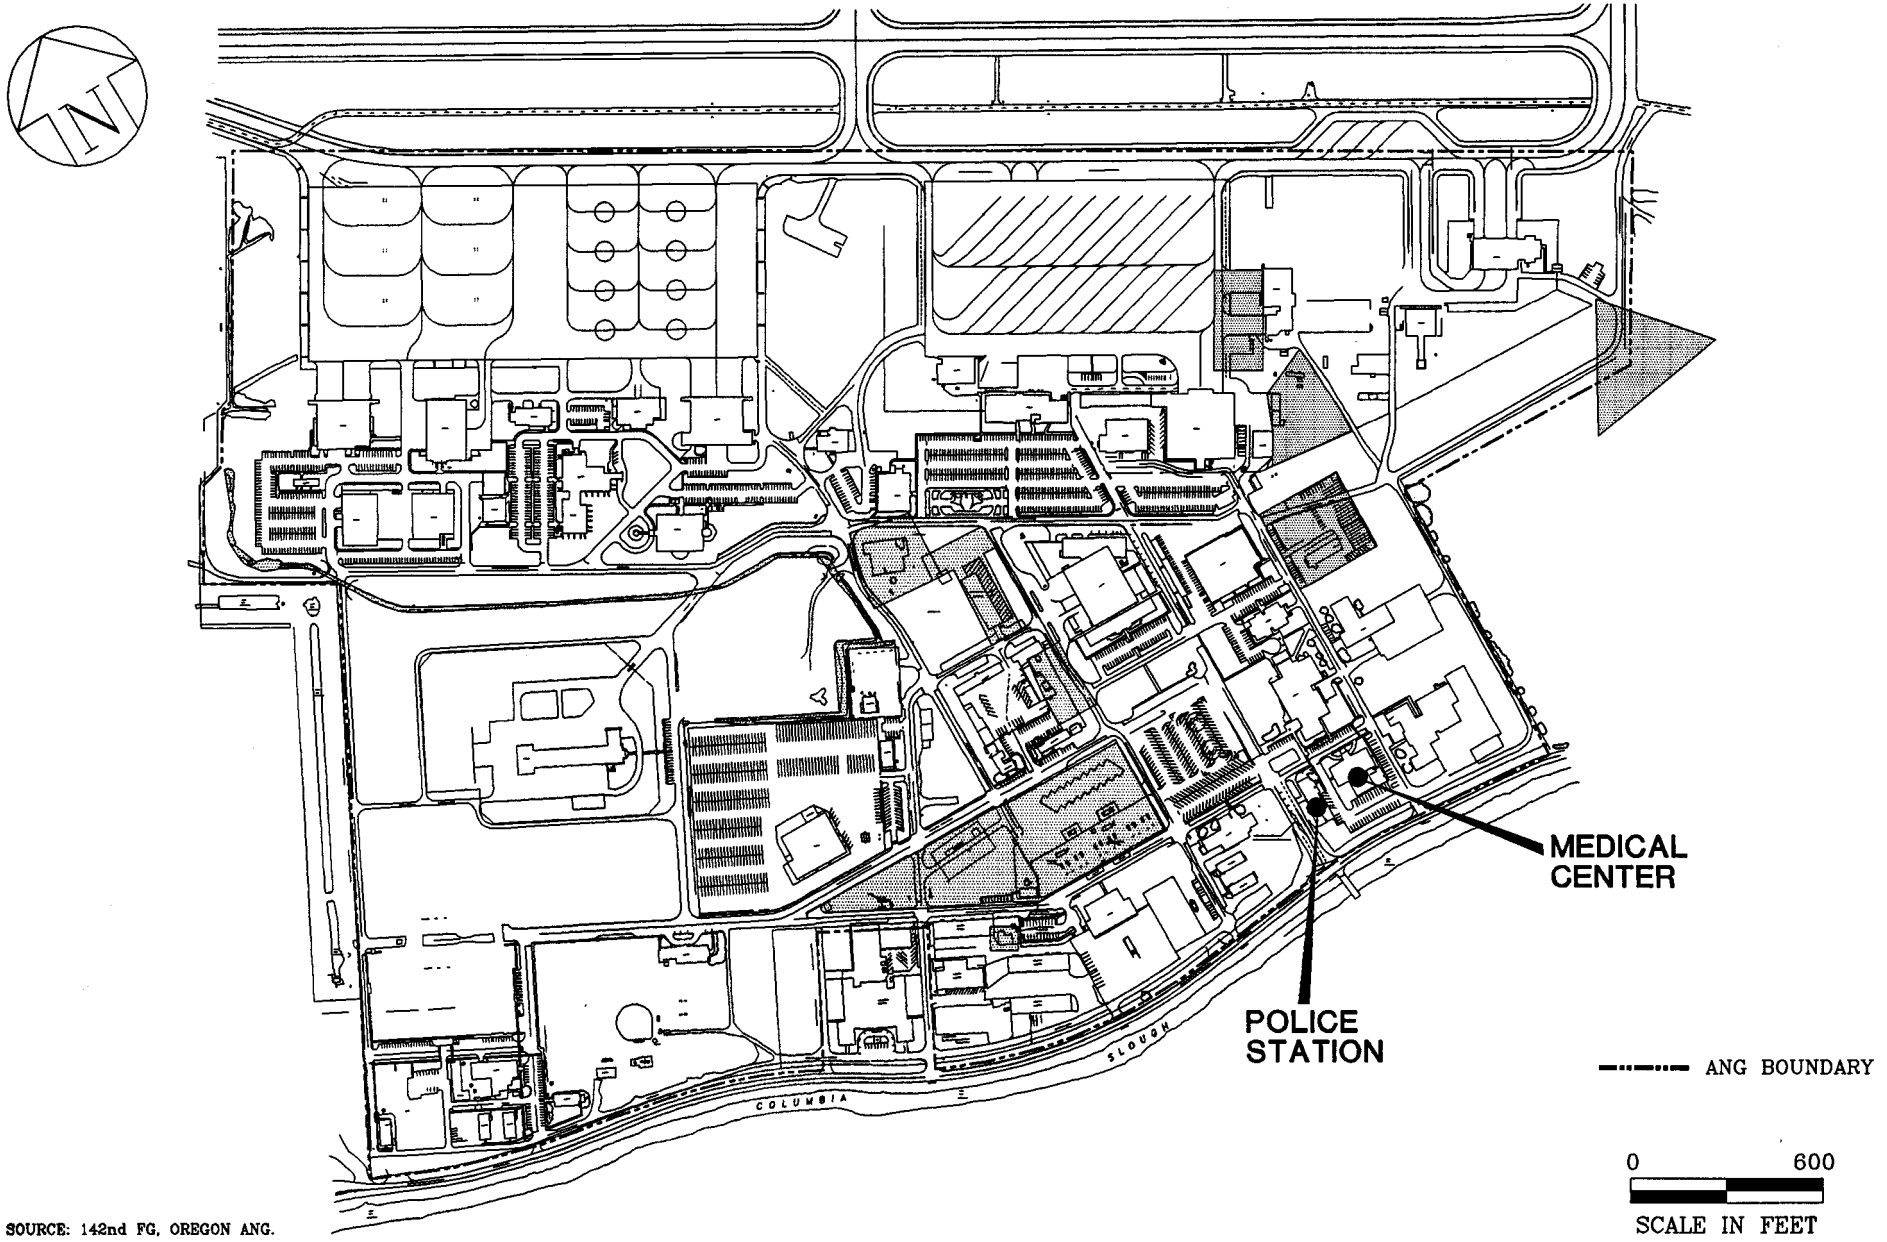
EMERGENCY CONTACTS



In the event of any situation or unplanned occurrence requiring assistance, the appropriate contact(s) will be made from the list below. For emergency situations, contact will first be made with the Field Team Leader, who will notify emergency personnel, and then contact the appropriate response teams. This emergency contacts list must be kept in an easily accessible location at the site.

142nd FG, Oregon ANGB Portland, Oregon
Emergency Contacts

Contact	Phone Number
Ambulance (on-base)	118
Ambulance (off-base)	911
Fire (on-base)	117
Fire (off-base)	911
Base Security	116
Woodland Park Hospital 10300 N.E. Hancock Portland, OR	503-257-5500
Major Roger Rein	503-335-4462
Jon Williams Site Health & Safety Coordinator	210-731-0000
OpTech Project Manager David Bunn	423-483-8020 1-800-983-4337

Route to Base Hospital:
In the event of an emergency, the nearest medical facility is located at Building 135. The location is shown on the map on the following page (Figure A.1).

Route to Medical Center:
The route to the nearest off-base hospital is shown on the following page (Figure A.2).
A detailed map will be posted during the investigation.

AIR MONITORING ACTION LEVELS

Concentration of Organic Vapors in Breathing Zone	Action
≥1 ppm Benzene	Stop work until levels dissipate or ventilate area
> 100 ppm* toluene, xylene, or ethylbenzene	Stop work until levels dissipate or ventilate area

* Based on Threshold Limit Value -- Time Weighted Average (TLV-TWA) exposure limits for toluene, xylene, and ethylbenzene, assuming benzene does not exceed 1 part per million (ppm).

EMERGENCY RESPONSE PLAN

The Contractor's policy will be to evacuate personnel from areas involved in hazardous material emergencies and to summon outside assistance from agencies with personnel trained to deal with the specific emergency. This section outlines the procedures to be followed by the Contractor's personnel in the event of a site emergency. These procedures are to be reviewed during the on-site safety briefings conducted by the Site Safety Officer (SSO).

Paramedics will be summoned in the event of a serious injury; they will arrange to transport the victim to the nearest appropriate facility. A first aid kit will be available at the site for use in case of minor injuries. If anyone receives a splash or particle in the eye, the portable eyewash will be used to irrigate the eye for 15 minutes. If direct contact with contaminants occurs, affected skin areas will be washed immediately with soap and water.

In the event of serious trauma or unknown chemical exposure, the employee should be stabilized by on-site personnel while the emergency phone number list is consulted and an ambulance immediately summoned.

Workers with suspected back or neck injuries are NOT to be moved until professional emergency assistance arrives.

At least one person at the site will have current certification in First Aid and Cardiopulmonary Resuscitation (CPR).

SECTION 1.0 INTRODUCTION

1.1 PURPOSE AND POLICY

The purpose of this Health and Safety Plan (HSP) is to establish personnel protection standards and mandatory safety practices and procedures for all work conducted at the 142nd Fighter Group (FG), Portland International Airport (PIA), Portland, Oregon. The plan assigns responsibilities, establishes standard operating procedures, and provides for contingencies that may arise while performing the field work.

1.2 APPLICABILITY

This plan was developed specifically for field operations at 142nd Fighter Group (FG), Oregon ANG, PIA, Portland, Oregon. This plan complies with, but does not replace, Federal Health and Safety Regulations as set forth in 29 Code of Federal Regulations (CFR) 1910 and 1926, and is to be used by all on-site personnel as a supplement to such rules, regulations, and guidance.

The provisions of the plan are mandatory for all on-site personnel engaged in hazardous material management activities, including, but not limited to: initial site reconnaissance, hydrogeologic and soil investigation, mobilization, project operations, and demobilization. All contractor and subcontractor personnel who engage in on-site project activities must be familiar with and comply with this plan. Any supplemental subcontractors' plans must conform to this plan.

1.2.1 Modification of Plan

Changing or unanticipated site conditions may require modification of this project safety plan in order to maintain a safe and healthful work environment. Any proposed changes to this plan should be reviewed with the Contractor Corporate Health and Safety Manager (CHSM) or designee, prior to change implementation. If this is not feasible, the Project Manager (PM) may modify the plan and record all changes in the site logbook. Under no circumstances will modifications to this plan conflict with Federal, state, or local health and safety regulations.

1.2.2 Contractor Responsibilities

Contractor will provide a copy of this HSP to each site subcontractor in order to fulfill its obligation under 29 CFR 1910.120(b) (15) to inform subcontractors of site hazards. Each

subcontractor shall provide a HSP for its employees covering any exposure to hazardous materials and shall complete all work in accordance with that plan. The subcontractor shall hold contractor harmless from, and indemnify it against all liability in the case of any injury. Contractor reserves the right to review and approve the subcontractor's plan at any time.

Subcontractors are responsible for supervising their employees and maintaining safe working conditions at the work site. Contractor, through its PM or SSO, reserves the right to suspend the subcontractor's site work and ask the subcontractor's personnel to evacuate the hazard area in the event of grossly inadequate health and safety precautions on the part of the subcontractor or the belief that the subcontractor's personnel are, or may be, exposed to an immediate health hazard.

Employees of subcontractors must have completed appropriate site safety training and medical evaluation prior to conducting work involving possible exposure to hazardous materials. It is the subcontractor's responsibility to provide the required level of training and medical evaluations to their employees.

Subcontractors are responsible for obtaining, maintaining, and properly utilizing their own safety equipment in accordance with their health and safety plan requirements. This includes personal protective equipment (PPE) such as respirators, disposable clothing, hard hats or other equipment detailed in the HSP. Subcontractors are responsible for performing respirator fit tests.

1.3 SITE DESCRIPTION AND LOCATION

The sites to be addressed at the 142nd FG include:

- IRP Site No. 1 - Central Hazardous Waste Storage Area;
- IRP Site No. 2 - Civil Engineering Hazardous Material Storage Area;
- IRP Site No. 3 - Hush House Area;
- IRP Site No. 4 - Main Drainage Ditch;
- IRP Site No. 5 - AGE Maintenance Shop;
- IRP Site No. 7 - Burn Pit Area
- IRP Site No. 8 - Sanitary Landfill;
- IRP Site No. 9 - Petroleum, Oil, and Lubricants (POL) Facility;
- IRP Site No. 10 - Equipment Washrack; and
- IRP Site No. 11 - Washrack West of Building 250.

The Base background soil and groundwater will also be investigated during the RI field activities.

1.4 SCOPE OF WORK

This field effort involves a remedial investigation of eleven sites at the 142nd FG. Monitoring wells will be installed for groundwater sampling, and soil and sediment, and surface water samples will be collected at some of the sites. Groundwater, surface water, sediments and soil samples will be analyzed to determine the nature and extent of contamination.

1.5 HEALTH AND SAFETY PLANNING

Skin contact with potentially contaminated soil or water will be minimized by wearing PPE. Inhalation of vapors during soil sampling will be minimized by air monitoring, engineering controls, and the use of respiratory protection if action levels are exceeded. Ingestion of contaminated materials will be minimized by the prohibition on eating, drinking, smoking, or applying cosmetics in the exclusion or contamination reduction zones, and by good personal hygiene during decontamination (i.e., thoroughly washing face and hands with soap and water).

A photoionization detector (PID) (with a 11.4 ultraviolet (UV) tube)/flame ionization detector (FID) instrument capable of detecting total volatile organic and chlorinated organic vapors will be used to monitor for organic and chlorinated organic vapors. The monitor will be used on a continuous basis, typically every five to ten minutes, to monitor in the immediate vicinity of the investigative operations.

If readings exceed an average of 5 parts per million (ppm) above background levels for more than five to ten minutes, under the SSO's direction, monitoring for benzene, carbon tetrachloride, toluene, xylene, or other compounds, and total volatile organic vapors in the breathing zone of the person working nearest the site, will start immediately. If the breathing zone readings indicate the benzene concentration is above 1 ppm, and/or the PID reading is above 100 ppm, personnel will don level C protective equipment. If PID readings exceed 500 ppm or 10 ppm benzene concentration is exceeded, all work will stop and personnel will evacuate. If readings reach action levels, the SSO will require appropriate PPE.

Table A.1.1 provides a list of chemicals which may be encountered at the site.

1.6 RESPONSIBILITIES

Contractor and all subcontractors involved in site activities are required to ensure that on-site employees, visitors, and their suppliers/vendors comply with the minimum standards set forth by the Occupational Safety and Health Administration (OSHA), with contractor's or the

Table A.1.1
Known/Suspected Chemicals of Concern
Oregon Air National Guard
Portland International Airport, Portland, Oregon

Chemicals	OSHA PELS C, ACGIH Levels, PPM	Physical Description	Health Effects (MSDS Remarks)	Physical Properties
Benzene	1 (50 = C,10 min.)	Colorless, aromatic odor	Irritate eyes, nose respiratory tract, nausea, carcinogen.	FP = 12°F UEL = 7.1% VP = 75mm LEL = 1.3%
1,1,1- TCE (Organic Solvent)	350 (IDLH - 1,000)	Colorless liquid with a mild chloroform-like odor	irritates eyes, skin, respiratory system; causes dizziness and liver damage	FP=? UEL=10.5% VP=58mm LEL=8%
1,2 - DCE (Organic Solvent)	200 (IDLH - 1,000)	Colorless liquid with a chlorinated solvent-like color	irritates nose, throat; causes vomiting and liver damage	FP=39°F UEL=12.8% VP=180-265mm LEL=5.6%
Toluene	50 (C=300, 500/10 min) (STEL - 150)	Colorless with aromatic odor	Dizziness, headache, confusion, weakness, fatigue	FP = 40°F UEL = 1.3% VP = 22mm LEL = 1.3%
Xylene	100 (200 = C, 10 min) (IDLH - 1,000)	Colorless with aromatic odor	Dizziness, excitement, drowsiness, irritate eyes, mucous membrane, headache	Varies with isomers (FP=81-90°F) FP = 59°F UEL = 6.7% VP = 7.1mm LEL = 1.0%
Methylene chloride	50 (IDLH - 2,500)	Colorless liquid	Irritation to eyes, skin, carcinogen. Physical weakness.	FP=-139°F VP = 350 mm UEL = 23% LEL = 13%
PCBs (Aroctor® 1254)	(OSHA - 0.5 mg/m^3) (IDLH - 5mg/m^3)	Colorless viscous liquid with a mild, hydrocarbon odor	Irritant to eyes and skin, carcinogen; liver damage	(VP - 0.001 mm) (FP - 50°F) (LEL & UEL - N/A)
Acetone	(OSHA PEL - 750 ppm) (IDLH - 2,500 ppm)	Colorless liquid w/ a fragrant mint-like odor	Irritant to eyes, nose, throat. Headaches, dizziness, CNS depressant	VP = 180mm FP = -140°F UEL = 12.8% LEL = 2.5%
Ethylbenzene	100 (IDLH = 2000)	Colorless, aromatic odor	Irritation, skin sensitization	FP = 84°F UEL = 7.1% VP = 8.8mm LEL = 1.3%

Chromium (Metal)	OSHA = 1 mg/m^3 IDLH = 25 mg/m^3	Blue - white to steel gray, lustrous, brittle, hard, odorless solid	irritant to eyes, skin, and lungs;	vp - 0 mm; mp - 345.2°F, LEL&UEL - N/A
Lead (Metal)	OSHA - 0.050 mg/m^3 IDLH - 100 mg/m^3	Heavy, ductile, soft, gray solid	Irritates eyes, gastrointestinal tract, CNS, kidneys;	vp - 0mm; mp - 621°F, UEL&LEL - N/A
Nickel (Metal)	OSHA - 1mg/m^3 IDLH - 10 mg/m^3	metal, lustrous, silvery, odorless solid	nasal cavities, lungs, skin, allergic asthma;	vp - 0mm; mp - 283.1°F; UEL&LEL - N/A
Zinc (Metal)	OSHA 5 mg/m^3 IDLH - 500 mg/m^3	White odorless solid	irritant to eyes, skin, nose, throat;	vp - 0mm; mp - 554°F; LEL&UEL - N/A

Notes:
PEL = Permissible Exposure Limit
VP = Vapor Pressure
C = Ceiling Level
mm = millimeters
PCBs = polychlorinated biphenyls
ACGIH = American Confined Governmental Industrial Hygienists
IDLH = level which is immediately dangerous to life and health
TCE = Trichloroethane
UEL = Upper Explosive Limit
MSD = Material Safety Data
CNS = Central Nervous System
ppm = parts per million
DCE = Dichloroethene
LEL = Lower Explosive Limit
°F = Degrees Fahrenheit
min = minutes
mg/m^3 = milligram/cubic meters
OSHA = Occupational Safety and Health Administration
FP = Flash Point
BP = Boiling Point
MP = melting point
STEL = Short term exposure limit
N/A = Not applicable

subcontractor's project HSP, and with applicable regulations issued by governmental entities. Contractor and subcontractors are required to know and comply with the safety regulations which apply to their operations.

1.7 PROJECT TEAM ORGANIZATION/KEY PERSONNEL

The project team will include a PM, Field Team Leader (FTL), SSO, and a field team involved in on-site investigations and operations. The following subsections describe their roles and responsibilities.

1.7.1 Project Manager

The PM shall direct on-site investigations and operational efforts. The PM may delegate all or part of these duties to the Field Team Leader. At the site, the PM, assisted by the SSO, has primary responsibility for:

- Ensuring that appropriate PPE and monitoring equipment are available and properly utilized by all on-site personnel;
- Establishing that personnel are aware of the provisions of this plan, are instructed in the work practices necessary to ensure safety, and are familiar with planned procedures for dealing with emergencies;
- Establishing that all field personnel have a minimum of 40 hours health and safety training, have appropriate medical clearances, and have been fit tested for the appropriate respirators;
- Ensuring that personnel are aware of the potential hazards associated with site operations;
- Monitoring the safety performance of all personnel to ensure that the required work safety practices are employed;
- Correcting any work practices or conditions that may result in injury or exposure to hazardous substances;

- Ensuring the completion of Safety Plan Acceptance Agreement forms by contractor's and subcontractor's personnel;

- Halting site operations, if necessary, in the event of an emergency or to correct unsafe work practices; and

- Reviewing and approving the project HSP.

1.7.2 Field Team Leader

The FTL shall assume all responsibilities of the PM when the PM is not on-site. In addition, the FTL will be responsible for:

- Acting as on-site liaison with the 142nd FG, Environmental Management personnel and regulatory agencies;

- Ensuring that all notifications to the state regulatory agencies, fire Marshall, and other agencies have been made;

- Confirming that all underground utilities have been located prior to drilling;

- Ensuring that all work is performed in accordance with regulations and industry standards; and

- Keeping detailed record of all site activities in a project logbook.

1.7.3 Site Safety Officer (SSO)

The SSO duties may be carried out by the PM or FTL. However, for the 142nd FG project, a full-time dedicated SSO will be in place. The SSO shall:

- Implement the project HSP and report any deviations from the anticipated conditions described in the plan to the PM;

- Determine that monitoring equipment is used properly and is calibrated in accordance with manufacturer instructions or other standards, and that results are properly recorded and filed;

- Verify with the contractor CHSM and Subcontractor's Safety Representative (SSR) that assigned personnel have health and safety training, fit-for-duty medical and training authorizations;

- Assume any other duties as directed by the PM;

- Be responsible for identifying site personnel with special medical problems (e.g., allergies, personnel on medication) in order to determine fitness for work;

- Be responsible for conducting daily safety meetings and completing the Site Safety Briefing Report;

- Provide ongoing review of the protection level needed as project work is performed, and inform the PM of the need to upgrade/downgrade protection levels as appropriate;

- Conduct daily "tailgate" safety briefing for all site personnel.

- Be responsible for monitoring and recording results of exposure evaluations;

- Halt site operations, if necessary, in the event of an emergency or to correct unsafe work practices;

- Prepare accident/incident reports; and

- Review and approve the project HSP.

1.7.4 Field Team

Project personnel involved in on-site investigations and operations are responsible for:

- Taking all reasonable precautions to prevent injury to themselves and to their fellow employees;

- Performing only those tasks that they believe they can do safely, and immediately reporting any accidents and/or unsafe conditions to the SSO or PM;

- Implementing the procedures set forth in the HSP, and reporting any deviations from the procedures described in the plan to the SSO or PM for action;

- Notifying the PM and SSO of any special medical problems (e.g., allergies) and insuring that all on-site personnel are aware of any such problems; and

- Reviewing the project HSP and signing the Safety Plan Acceptance Agreement Form.

1.8 SUBCONTRACTOR SAFETY REPRESENTATIVE

Each subcontractor is required to designate an SSR. The SSR is responsible for the safe and healthful performance of work by his work force and subcontractors. During the subcontractor activities on-site, the SSR will perform continuing work area inspections, and conduct safety meetings and safety orientations for all new employees. The SSR and all other personnel on site will attend mandatory daily "tailgate" periodic safety meetings. The SSR will also investigate accidents and overexposures involving subcontractor personnel.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 2.0 SAFETY AND HEALTH RISK ANALYSIS

2.1 CHEMICAL HAZARDS

A number of materials containing hazardous chemicals may be encountered at the site. These known/suspected chemicals were previously identified in Table A.1.1. Detailed information on the nature of the hazards presented by these chemicals is found on the Material Safety Data Sheets (MSDS). Compounds in concentrations that exceed health exposure standards may be present in the soil and groundwater. Primary routes of exposure for these chemicals are inhalation, skin absorption, and eye contact. Symptoms of exposure can range from none to irritation of the eyes, nose, and respiratory system; headache; staggered gait; fatigue; and dermatitis. Permissible exposure limits and other properties of compounds which may be encountered are shown in Table A.1.1.

Overviews of the hazards associated with exposure to the chemicals found on-site to date are presented below in terms of:

PEL	Permissible Exposure Limit
C	Ceiling
TLV	Threshold Limit Value (American Conference of Governmental Industrial Hygienists (ACGIH) Guidance)
TLV-STEL	Threshold Limit Value - Short Term Exposure Limit (ACGIH, Guidance)
LEL	Lower Explosive Limit

OSHA PELs, ACGIH TLVs, and TWAs are defined as concentrations for an 8-hour work day, 40-hour work week to which almost all workers can be repeatedly exposed without suffering adverse health effects.

A ceiling (C) value is a concentration that should not be exceeded at any time in any work day.

STEL is defined as the concentration to which workers can be exposed for short time periods without irritation, tissue damage, or narcosis sufficient to cause impairment of self-rescue or precipitate accidental injury. It is a 15-minute TWA that should not be exceeded at any time during the work day.

LEL is defined as the minimum concentration of vapor in air below which propagation of a flame will not occur in the presence of an ignition source.

The following potential exposures may exist at the site:

- Skin contact with contaminated soil or water;
- Inhalation of vapors; and
- Ingestion of contaminated soil dusts, especially if poor personal hygiene is practiced.

Skin contact with potentially contaminated soil or water will be minimized by wearing personal protective equipment (as described in Section 3.8 of the HASP). Inhalation of vapors during excavation or soil and groundwater sampling will be minimized by air monitoring, engineering controls, and the use of respiratory protection if action levels are exceeded. In order to prevent ingestion of contaminants, proper decontamination and personal hygiene are required. Eating, drinking, chewing tobacco or gum, smoking, or applying cosmetics is prohibited.

2.2 PHYSICAL HAZARDS

2.2.1 Construction Hazards

Employees must implement safe work practices in accordance with OSHA regulations while working on-site. In addition to the hazardous substances and environments present on-site, other physical hazards may exist, including risk of injury while working in or around heavy equipment. Work areas will be barricaded to protect both public and operational personnel.

2.2.2 Heavy Equipment

Operation of heavy equipment, such as drilling rigs and the GeoProbe™, presents potential physical hazards to personnel. PPE such as steel-toed shoes, safety glasses or goggles, and hard hats must be worn whenever such equipment is present. Personnel should at all times be aware of the location and operation of heavy equipment, and take precautions to avoid getting in the way of their operation.

2.2.3 Noise Hazards

The primary noise hazard at the site will be noise from operating heavy equipment. All personnel are required to have ear protection (either muffs or plugs) when conducting field activities, and ear protection will be worn within 25 feet of operating equipment. An exclusion zone surrounding the operating equipment will be roped off to prevent access to any unauthorized personnel. The FTL and SSO will determine and enforce any other noise protection requirements deemed appropriate. All contractor and sub-contractor field personnel will have undergone an annual medical examination which included an audiogram conducted by a licensed occupational health physician in accordance with 29 CFR 1910.95, Hearing Conservation.

2.2.4 Fire/Explosion

Field activities could cause sparking. Flammable liquids are present in the form of diesel and gasoline for operation of equipment, and potentially petroleum wastes and solvents. A PID, oxygen $(O)_2$ meter, and an combustible gas indicator (CGI) should be used to monitor the work area atmosphere, as determined by the PM and SSO.

2.2.5 Heat Stress

Heat stress may be of concern, depending on ambient temperature, work load, PPE, and radiant heat. Working in PPE can greatly increase the likelihood of heat fatigue, heat exhaustion, and heat stroke; the latter being a life-threatening condition. Work/rest schedules will be implemented within the guidelines of the American Conference of Governmental Industrial Hygienists, Wet Bulb Globe Temperature (WBGT) TLVs. The SSO will be responsible for briefing workers on the signs of heat stress when weather conditions require it. This should be done during the daily tailgate meeting. The SSO is responsible for stopping work should ambient temperature conditions warrant.

2.2.6 Prevention of Heat Stress

Proper training and preventive measures will aid in averting loss of worker productivity and serious illness. Heat stress prevention is particularly important because, once a person suffers from heat stroke or heat exhaustion, that person may be predisposed to additional heat-related illness. The "buddy system" should be utilized to watch for signs of heat stress. To avoid heat stress, the following steps should be taken:

- Adjust work schedules.
- Modify work and rest schedules according to monitoring requirements.
- Mandate work slowdowns as needed.
- Provide shelter or shaded areas to protect personnel during rest periods.
- Maintain worker body fluids at normal levels. The normal thirst mechanism is not sensitive enough to ensure that enough water will be drunk to replace lost sweat. When heavy sweating occurs, encourage the worker to drink fluids frequently.

2.2.7 Heat Exhaustion

Heat exhaustion occurs from increased stress on various body organs, including inadequate blood circulation due to cardiovascular insufficiency or dehydration. Symptoms of heat exhaustion include extreme fatigue, cramps, dizziness, headache, nausea, profuse sweating; pale, cool moist skin; core body temperature > 100.4° Fahrenheit (°F) (38° Celsius (°C)). Treatment of heat exhaustion requires immediately removal of the victim from the work area. Allow victim to rest, cool off, and drink plenty of cool water. If the symptoms do not subside after a reasonable rest period, employees shall notify the SSO and seek medical assistance.

2.2.8 Heat Stroke

Heat stroke is the most serious form of heat stress. Temperature regulation fails and the body temperature rises to critical levels. Immediate action must be taken to cool the body before serious injury or death occurs. Symptoms of heat stroke include body temperatures between 105-107° F. Initial symptoms often include red, hot, dry skin; lack of or reduced perspiration; nausea; dizziness and confusion; strong, rapid pulse; coma. Unconsciousness follows quickly and death is imminent if exposure continues. The attack will usually occur suddenly. It is imperative that competent medical help be obtained ***immediately.***

2.2.9 Cold-Related Illness

In the winter months, thermal injury due to cold exposure can become a problem for field personnel. Systemic cold exposure is referred to as hypothermia, while local cold exposure is generally labeled frostbite.

- Hypothermia is defined as a decrease in the patient core temperature below 96°F. Symptoms of hypothermia include shivering, apathy, listlessness, sleepiness, and unconsciousness.

- Frostbite is both a general and medical term given to areas of local cold injury. Unlike systemic hypothermia, frostbite rarely occurs unless the ambient temperatures are less than freezing and usually less than 20°F. Frostbite produces a sudden blanching or whitening of the skin; the skin has a waxy or white appearance and is firm to the touch; tissues are cold, pale, and solid.

2.2.10 Prevention of Cold-Related Illnesses

- Educate workers to recognize the symptoms of frost-bite and hypothermia;
- Identify and limit known risk factors
  - •• Prohibit the use of phenothiazine (a sedative)
  - •• Identify/warn/limit use of beta blockers on back
- Assure the availability of enclosed, heated environment on or adjacent to the site
- Develop capability for temperature recording at the site

2.3 BIOLOGICAL HAZARDS

2.3.1 Ticks and Lyme Disease

Lyme Disease is most prevalent in the eastern United States. Deer ticks are believed to be the main carrier of the disease. Deer ticks have been found on and spread by deer, household pets, birds, and other warm-blooded animals. Lyme disease is associated with bites from deer ticks.

Authorities believe the ticks have to be attached for many hours to transmit the infection. At the end of the day, do a self examination for ticks. Ticks range from pinpoint size to over one-quarter of an inch in diameter. Ticks have a flat body, unless gorged with blood, and have an appearance

which resembles a miniature crab. If found, ticks should be pulled off using tweezers. Removal should be performed by firmly grasping the tick with tweezers and pulling carefully and steadily. The infecting organism is located in the midgut of the tick so authorities say that it is not cause for alarm if some of the head remains under the skin.

Lyme disease causes fever, headaches, fatigue, and pain or stiffness in muscles and joints. If untreated, it can also bring lifelong impairment of the muscular or nervous systems including chronic arthritis or brain injury. About 10% of the people develop crippling arthritis. There are three stages of Lyme disease, but any one can occur without the preceding one(s).

- Stage 1: Flu-like symptoms accompanied by a skin rash with a bright red border. Symptoms go away after a few days to a few weeks. There is a strong chance that the symptoms will reoccur later. Treatment: Antibiotics to destroy the infection.

- Stage 2: Weeks or months after the bite, symptoms marked by irritability, stiff neck, and difficulty concentrating. These symptoms are signs of nervous system damage which could lead to meningitis. Pain in the elbow and/or knees sometimes occurs; the pain may alternate between the joints.

- Stage 3: Chronic problems including arthritis, numbness, tingling or burning sensations. The symptoms can occur on the trunk of the body, the extremities, or the brain. The more serious nervous system damage is believed to be uncommon.

Prevention of Lyme disease consists of repelling ticks and of preventing tick bites. The only recognized repellent is N,N-diethyl-m-toluamide (DEET). DEET is generally considered to be safe and is used in a variety of over-the-counter insect and tick repellents. The brand of insect repellant called "OFF' uses carrier solvents which will not interfere with volatile organic analysis scans at the site. DEET should be applied to exposed skin and to disposable coveralls worn over street clothes. Additionally, long pants should be worn and the pant legs tucked into the socks to make it difficult for ticks to reach the skin.

There are reports of uncommon side effects from DEET which include one or more of the following symptoms: skin irritation, slurred speech, confusion, and seizures. In the event that any of the above symptoms occur, DEET should be promptly removed with soap and water. If

symptoms persist, seek medical attention. In any case, DEET should be washed off at the end of the work day to minimize potential for skin irritation or other side effects.

2.3.2 Poisonous Plants

Poison ivy and poison oak may be present at the site. Personnel should avoid contact.

2.3.3 Animals

It is possible that poisonous snakes could occur in the 142nd FIG area. Personnel entering overgrown areas should wear snake chaps or gaiters.

Insects such as bees and wasps may be found on-site. Personnel who may have allergic reactions should keep their personal first aid kit on-site.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 3.0 PERSONNEL PROTECTION AND MONITORING

3.1 MEDICAL SURVEILLANCE

All personnel on the site will have successfully completed a preplacement or periodic/update physical examination within the last 12 months. This examination will comply with 29 CFR 1910.120 medical requirements for hazardous waste site workers. Documentation of this examination for all site personnel will be maintained by the SSO.

The suggested medical surveillance program examination may consist of:

- Medical and occupational history form;
- Physical examination;
- Selected biological sampling;
- Complete blood count (CBC) with differential;
- Urinalysis;
- Chemistry panel (SMAC);
- Chest X-ray;
- Pulmonary function test (forced expiratory volume/forced vital capacity);
- Audiogram;
- Electrocardiogram;
- Visual acuity; and
- Ability to wear respirator.

The following information must be provided to the examining physician:

- Description of the employee's duties;
- Anticipated exposure types and levels; and
- Information from previous medical exams.

All workers who have potential for exposure to hazardous materials shall have successfully completed an examination similar to the preplacement physical. All examinations should be approved by a physician who is Board Qualified in Occupational Medicine by the American Board of Preventive Medicine/Occupational Medicine. The physician shall provide to the employer written certification of site personnel as fit for duty per 29 CFR 1910.120.

3.1.1 Requirement for Contractor Personnel

Contractor employs the services of a licensed occupational health physician with knowledge and experience in the hazards associated with the project to provide the medical examinations and surveillance herein.

Personnel involved in this project shall have undergone regular medical examinations at 12-month intervals. The medical exam is performed under the direction of a licensed occupational health physician. A medical evaluation of fitness or unfitness of an individual for employment on hazardous waste projects, or any restriction on that person's utilization that may be indicated, is provided by the physician.

3.1.2 Requirement for Subcontractors

Subcontractors shall be responsible for medical surveillance of their employees and providing documentation to contractor's SSO.

3.2 TRAINING REQUIREMENTS

3.2.1 Introductory And Refresher Training

In compliance with Code of Federal Regulations (CFR) 29 CFR 1910.120(e), site workers will have taken the required 40 hour Hazardous Waste Operations and Emergency Response course before working on this project. If 1 year or more has elapsed since successful completion of the 40 hour course, workers must have completed the 8-hr annual update training required of hazardous waste site personnel. Workers will also have had 3 days of actual field experience on a hazardous waste site under the supervision of a trained, experienced supervisor before beginning work. Any workers who will be exposed to unique or special hazards will be provided with additional training relevant to these hazards.

Supervisory personnel will have met the same basic training and experience requirements as other site workers. In addition, they will have received 8 hours of training in management of hazardous waste site operations.

All on-site supervisors and workers will be enrolled in a medical surveillance program. Enrollment in a medical surveillance program is required by 29 CFR 1910.120(f).

3.2.2 Site-Specific Training

The SSO will be responsible for developing a site-specific occupational hazard training program and providing training to all contractor personnel who are to work at the facility. This training will consist of the following topics:

- Names of personnel responsible for site safety and health;
- Safety, health, and hazards at the site;
- Proper use of PPE;
- Work practices by which the employee can minimize risk from hazards;
- Safe use of engineering controls and equipment on the site;
- Acute effects of contaminants at the site; and
- Decontamination procedures.

3.2.3 Daily Briefing Sessions

The SSO will conduct brief (5- to 10-min) on-site briefing sessions at the beginning of each workday. These "tailgate" meetings will focus on tasks scheduled for that day and health and safety issues pertinent to those tasks. All briefings, job-specific safety topics, and personnel attendance lists shall be documented in the field notebook.

3.2.4 Requirements For Subcontractors

Subcontractors are responsible for providing required training to their employees. Documentation and certification must be provided to contractor's SSO.

3.3 PERSONAL PROTECTIVE EQUIPMENT AND ACTION LEVELS

Level D protection will be worn for initial entry on site and initially for all activities. Level D protection consists of:

- Standard work clothes. Tyvek coveralls are optional if there is a possibility of contact with contaminated soils;
- Safety glasses;
- Steel-Toe Safety boots;
- Nitrile, latex, or vinyl gloves - mandatory during all sampling activities; and
- Hard Hat.

Level C protection will be worn in the event activities *must* be performed in the presence of organic vapors in excess of 100 ppm. Level C protection consists of all level D equipment, plus negative-pressure respirators equipped with organic vapor cartridges. Organic vapors in excess of 500 ppm or benzene concentrations in excess of 10 ppm will require evacuation of work area.

3.4 MONITORING REQUIREMENTS

3.4.1 Routine Monitoring for Organic Vapors

Benzene has the lowest PEL - 1 ppm - of all of the suspected contaminants on site. Specific monitoring for airborne benzene will be performed daily during field activities using Draeger tubes with pretubes. In the event benzene is detected at or in excess of 1 ppm, work at the site will be suspended. Should these levels dissipate, work will continue; if the levels persist, ventilation of the area by fans will be evaluated.

Negative-pressure respirators equipped with organic vapor cartridges will be kept on hand for emergency purposes. In the event that benzene levels are between 1 ppm and 10 ppm, or total organic vapors exceed 100 ppm and levels do not dissipate, emergency activities will be performed in Level C protection until fans are brought on site.

Monitoring for organic vapors in the breathing zone will be conducted with organic vapor detection equipment. Readings will be taken under the following circumstances:

- Upon initial entry onto the site;
- When weather conditions change;
- While work is in progress on the site; and
- When work begins on another portion of the site.

3.4.2 Routine Monitoring for Explosive Environment

Air monitoring will be conducted for combustible gases and vapors. A combustible gas indicator is the instrument of choice in determining the concentration of flammable vapor in the air. Guidelines have been established by the National Institute for Occupational Safety and Health (NIOSH) concerning the action levels to be utilized when working in a potentially explosive environment. A combustible gas indicator/O_2 meter will be used to monitor ambient conditions at all times during drilling operations. Oxygen concentrations should be measured prior to taking combustible readings to determine if there is sufficient oxygen (10%) to operate the combustible gas indicator.

The combustible gas indicator is intended for use only in normal atmospheres, not those that are oxygen enriched or deficient. Oxygen concentrations that are less than or greater than normal may cause erroneous readings.

All monitoring equipment used during these studies must be certified for operation in a class I atmosphere. A class I atmosphere consists of flammable vapors and gases, such as gasoline and hydrogen. The instrument's instruction manual contains information on the use of the instrument in an explosive atmosphere.

NIOSH guidelines on the use of the combustible gas indicator:

LEL Reading	Action
< 10% LEL	Continue operations
10% - 20% LEL	Increase Monitoring Frequency
> 20% LEL	Shut down operations and evaluate source, ventilate.

When readings exceed 20 percent LEL on the indicator, *all activities must cease* to allow time for the combustible gases to dissipate.

3.4.3 Oxygen Monitoring

NIOSH requires the use of self-contained breathing apparatus when oxygen concentrations fall below 19.5 percent. This condition is not likely be encountered, since there should be no activities performed in confined work spaces. However, should the situation change, an oxygen indicator should be used to monitor the atmosphere oxygen concentration during site activities. Prior to entering an excavation or tank, an oxygen meter will be used to test for adequate oxygen levels. Decisions will be based on oxygen concentrations as followed:

OXYGEN Concentration	Action
20.8%	Continue operations
< 20.8%, but > 19.5%	Continuous Monitoring of O_2 Concentrations
< 19.5%	Do not enter, ventilate, and determine if supplied air is required

3.4.4 Monitoring for Heat Stress

Monitoring of personnel wearing personal protective clothing should commence when the ambient temperature is 70°F or above. Monitoring frequency should increase as the ambient temperature increases or as slow recovery rates are observed. Heat stress monitoring will be performed by a person with a current first aid certification who is trained to recognize heat stress symptoms. Heat stress of employees on site will be monitored by the WBGT index technique. This method requires the use of a heat stress monitoring device, such as the Reuter-Stoked Wibget Heat Stress Monitor. Heat stress of employees on site will be monitored by the SSO.

Note: Three to five degrees C must be subtracted from the WBGT TLV when wearing impermeable protective clothing. Once the initial work/rest regimen has been established, physiological monitoring (heart rate) may be conducted by the SSO to adjust the work/rest regimen. The SSO will make the appropriate adjustments.

To monitor the worker, one of the following methods may be used:

- Heart rate: Count the radial pulse during a 30-second period as early as possible in the rest period. If the rate exceeds 100 beats per minute at the beginning of the rest period, shorten the next work cycle by one-third and keep the rest period the same. If the heart rate still exceeds 100 beats per minute at the next rest period, shorten the following work cycle by one-third.

- Oral temperature: Use a clinical thermometer (3 minutes under the tongue) or similar device to measure the oral temperature at the end of the work period (before drinking).

- If oral temperature exceeds 99.6°F (37.6°C), shorten the next work cycle by one-third without changing the rest period.

- If oral temperature still exceeds 99.6°F (37.6°C) at the beginning of the next rest period, shorten the following cycle by one-third.

- Do *not* permit a worker to wear a semipermeable or impermeable garment when oral temperature exceeds 100.6°F (38.1°C).

Suggested frequency of physiological monitoring of workers is shown on Table A3.1.

Table A3.1 Suggested Frequency of Physiological Monitoring for Workers[1,2]

Adjusted Temperature[3]	Normal Work Ensemble[4]	Impermeable Ensemble
87.5°-90°F (30.8°-32.2°C)	After each 60 minutes of work	After each 30 minutes of work
82.5°-87.5°F (28.1°-30.8°C)		After each 60 minutes of work
77.5°-82.5°F (25.3°-28.1°C)		After each 90 minutes of work
72.5°-77.5°F (22.5°-25.3°C)		After each 120 minutes of work

1 Source: *Occupational Safety and Health Guidance Manual for Hazardous Waste Site Activities*. (NIOSH 1985)

2 For work levels of 250 kilocalories/hour.

3 Calculate the adjusted air temperature (ta adj) by using this equation: ta adj°F = ta°F + (0.13 x % sunshine). Measure air temperature (ta) with a standard mercury-in-glass thermometer, with the bulb shielded from radiant heat. Estimate percent sunshine by judging what percent of the time the sun is not covered by clouds that are thick enough to produce a shadow. (100 percent sunshine = no cloud cover and a sharp, distinct shadow; 0 percent sunshine = no shadows.)

4 A normal work ensemble consists of cotton coveralls or other cotton clothing with long sleeves and pants.

3.4.5 Monitoring for Cold-Related Illness

Start oral temperature recording at job site:

- At the FTL's discretion when worker's performances or mental status changes in a manner which may indicate cold-related illness.
- At worker's request.
- As a screening measure, two times per shift, under unusually hazardous conditions (e.g., wind chill less than 20°F, or wind chill less than 30°F with precipitation).
- As a screening measure whenever any one worker on the site develops hypothermia.

Any person developing moderate hypothermia (a core temperature of 92°F) cannot return to work for 48 hours.

3.5 BACKGROUND READINGS

All direct-reading instrument readings will be evaluated relative to background readings, not "zero". Prior to the start of work at each shift, and whenever there is a significant shift in wind direction, instrument readings will be obtained upwind of the site operating zone in order to determine the level of "background" readings from local vehicle traffic, emissions from nearby operations unrelated to the site, etc. Site readings will be evaluated against these background readings.

3.6 DATA LOGGING

All exposure monitoring data, background readings, and daily instrument calibrations will be logged in the field log book. All monitoring instruments will be calibrated, in accordance with the manufacturer's instructions prior to the start of each shift and when inconsistent or erratic readings are obtained. If an instrument cannot be calibrated to specification, or becomes otherwise inoperable, all site work will cease until the instrument is appropriately repaired or replaced.

3.7 DUST CONTROL

If drilling operations generate a sustained visible dust cloud, a water mist will be applied to reduce dust generation. If the mist is not effective in reducing dust generation, personnel will don respirators (half-face or full-face as appropriate for analyzer readings) with combination organic vapor - high efficiency particulate air (HEPA) filter cartridges (such as Mine Safety Appliance's GMC-H cartridges).

3.8 PERSONAL PROTECTIVE EQUIPMENT

Minimum Protective Equipment for Site Personnel:

- Hardhat
- Safety glasses
- Steel-toed boots

Work/Exclusion Zone Requirements:

- Hardhat
- Eye protection (face shield or safety glasses)
- Chemical-resistant steel-toed boots
- Ear protection in vicinity of heavy equipment
- Work gloves
- Coveralls

These are standard for hazardous material contact:

- Tyvek coveralls or only needed if contact is possible
- Nitrile gloves
- Surgical latex or vinyl gloves

If analyzer reading greater than 100 ppm in breathing zone, add:

- Half-face respirator with organic vapor cartridges

If analyzer reading greater than 500 ppm in breathing zone, add:

- Full-face respirator with organic vapor cartridges

If potential for liquid contact exists:

- Use poly-coated Tyvek coveralls in place of uncoated Tyvek

SECTION 4.0 SITE CONTROL MEASURES, ACCIDENT PREVENTION, AND CONTINGENCY PLAN

4.1 SITE CONTROL MEASURES

The site control measures discussed in this section will be followed to minimize potential contamination of workers, protect the public from potential site hazards, and to control access to the sites. Site control involves the physical arrangement and control of the operation zones and the methods for removing contaminants from workers and equipment. Site organization is discussed in this section.

Barricades and barricade tape should be used to delineate an exclusion zone around the drilling area. The barriers should be set in a 25-foot radius (as practical) around the work area. A short piece of barricade tape can be affixed to an equipment cab to serve as a wind-direction tell-tale. A five-foot opening in the barricades at the support zone (upwind of the equipment) will serve as the personnel and equipment entry and exit point. The personnel decontamination station will be established at this point. All entry to and exit from the drilling work area will be made at this opening in order to control potential sources of contamination (i.e., leave contaminated soil and debris in the exclusion area).

At the end of the shift, the site must be barricaded or otherwise secured. All soils are to be placed on plastic and covered. All decontamination fluids are to be drummed, and the drums shall be properly marked and labeled in accordance with applicable Department of Transportation (DOT) regulations (49 CFR 172).

The PM or SSO will determine an upwind evacuation area prior to each shift, and all personnel will be notified of its location. A compressed gas horn will be used to signal an evacuation in the event of an emergency. Three blasts of the horn will be the signal to immediately stop work and proceed to the evacuation area.

The SSO will ensure that all site visitors are logged in the project log book and that all personnel who enter the work zone do so only with permission of the SSO and after a field briefing of the current activities and potential site hazards.

4.2 SITE ORGANIZATION-OPERATION ZONE

Any time respirators are worn, the following operation zones will be established on the site or around the tanks.

- Exclusion zone (contamination zone)
- Contamination reduction zone
- Support zone

If the field crew members are wearing protective clothing such as gloves or Tyvek suits but are not wearing respirators (level D modified), the field crew will establish a decontamination area to avoid spreading contaminants off site. The FTL and/or SSO is responsible for establishing the size and distance between zones at the site or around the site feature.

4.3 WORK ZONES

4.3.1 Exclusion Zone (Contamination Zone)

The exclusion zone constitutes the place where active investigation or cleanup operations take place. Within the exclusion zone, prescribed levels of protection must be worn by all personnel. The hotline, or exclusion zone boundary, is initially established based on the presence of actual wastes or apparent spilled material, or through air monitoring. The hotline is placed around all physical indicators of hazardous substances (drums, tanks, ponds, liquid runoff, defoliated areas). The hotline may be readjusted based on subsequent observations and measurements. The boundary should be physically secure and posted or well defined by physical and geographic limits.

- Exclusion zone - A 25-foot (as practical) circle around the site will be defined before work starts. The encircled area will constitute the "Exclusion Zone". This zone is where potentially hazardous contaminants and physical hazards to the workers will be contained. Full personal protection may be required in this area. Plastic sheeting (visqueen) and/or tarps will be used to control cuttings or spoils spilled, or placed on the ground during drilling operations. The size of the Exclusion Zone may be altered to accommodate site conditions and to ensure contaminant containment.

Under some circumstances, the exclusion zone may be subdivided into zones based on environmental measurements of expected onsite work conditions.

4.3.2 Contamination Reduction Zone

Between the exclusion zone and the support zone is the contamination reduction zone. This zone serves to prevent or reduce the transfer of hazardous materials which may have been picked up by personnel or equipment leaving the exclusion zone.

- Contamination Reduction Zone (CRZ) - A corridor leading from the Exclusion Zone will be defined, and will lead from the work area to a break area. All decontamination activities will occur in this area. A waste container will be placed at the end of the corridor so contaminated disposal equipment can be placed inside and covered. Surface/soil contamination in this area should be controlled using plastic sheeting. CRZ or Exclusion Zone entry requires permission from the SM or SSO.

4.3.3 Support Zone

The support zone is the outermost area of the site and is considered a noncontaminated or clean area. The support zone contains the command post for field operations, first aid stations, and other investigation and cleanup support. Normal work clothes are appropriate apparel within this zone; potentially contaminated personnel clothing, equipment, etc., are not permitted.

- Support Zone - a Support Zone, the outermost part of the site, must be defined for each field activity. Support equipment is located in this uncontaminated or clean area. Normal work clothes are appropriate within this zone. The location of this zone depends on factors such as accessibility, wind direction (upwind of rig), and resources (i.e., roads, shelter, utilities).

4.4 SAFE WORK PRACTICES

To ensure a strong safety awareness program during drilling operations and monitoring well construction, personnel must have adequate training, this HASP must be communicated to the

employees and visitors, and standing orders must be developed and communicated to visitors and employees. Standing orders for personnel entering the exclusion zone are as follows:

- Eating, drinking, chewing gum or tobacco, and smoking are prohibited in the contaminated or potentially contaminated area of where the possibility for the transfer of contamination exists.

- No matches or lighters in zone.

- No personal vehicles are allowed in either the exclusion or contamination reduction zones.

- Check in and check out at access control points.

- The buddy system will be used at all times when performing sampling for hazardous material when the first action level criterion has been exceeded.

- All PPE will be used as specified and required.

- Avoid contact with potentially contaminated substances. Do not walk through puddles, pools, mud, etc. Avoid, whenever possible, kneeling on the ground, leaning or sitting on equipment or ground. Do not place monitoring equipment on potentially contaminated surfaces.

- Discovery of unusual or unexpected conditions will result in immediate evaluation and reassessment of site conditions and health and safety practices.

- Conduct safety briefings prior to onsite work.

- Take precautions to reduce injuries from heavy equipment and other tools.

- All field crew members should make use of their senses to alert them to potentially dangerous situations in which they should not become involved (i.e., presence of strong, irritating or nauseating odors).

- Prevent, to the extent possible, spillages. In the event that a spillage occurs, contain liquid if possible.

- Prevent splashing of the contaminated materials.

- Field crew members shall be familiar with the physical characteristics of investigations, including:

  - Wind direction in relation to contaminated area

  - Accessibility to equipment and vehicles

  - Communications

  - Hot zone (areas of known or suspected contamination)

  - Site access

  - Nearest potable water sources

- The number of personnel and equipment in the contaminated area should be minimized but only to the extent consistent with workforce requirements of safe site operations.

- All wastes generated during Field Activities at the Base will be disposed of as directed by the PM.

The following guidelines will be followed while working on site:

- Heavy equipment: Only qualified operators will be allowed to operate heavy equipment. Subcontractors will be required to use the safe work guidelines included in the OSHA General Industry (29 CFR 1910) and Construction Industry (29 CFR 1926) Standards.

- Trench shoring: Any trenches for human entry will be shored or have the sides laid back in accordance with 29 CFR 1926 subpart P and certified by a Professional Engineer. All trenching and shoring will be inspected daily by the SSO.

- Power lines: When operating heavy equipment, such as drilling rigs near power lines, workers will take care to ensure that the boom or rigging always maintains a safe distance from power lines (20 feet minimum). Any underground utility lines must also be located and appropriate precautions taken before any drilling is done.

- Swing radius: All swing equipment, such as cranes or backhoes, will have the swing radius guarded to prevent workers from being struck by the rotating machinery.

- Electrical equipment: All electrical equipment will be properly grounded and class approved for the location.

- Machine guarding: All machinery on site will be properly guarded to prevent contact with rotating shafts, blades, or gears.

- Flammable materials: When work involves flammable materials, adequate ventilating and control of all ignition sources will be maintained. This may include:

  - Nonsparking tools

  - Explosion proof equipment (intrinsically safe)

  - Class-approved electrical equipment

  - No smoking or open lights

  - No welding

4.5 HEALTH AND SAFETY EQUIPMENT CHECKLIST

The following list included normal health and safety equipment taken to the field:

Hard hats
Safety glasses
Ear plugs or muffs
Tyvek and polycoated Tyvek coveralls
Chemical resistant steel-toed boots
Work gloves
Nitrile gloves
Surgical vinyl, nitrile, or latex inner gloves
Plastic sheeting (visqueen)
55-gal 17-H drums (for contaminated solids) and 17-E drums (for liquids)
Drum liners
Barricade tape and barricades
Wash tubs and scrub brushes
Decon solution
Folding chairs
5- or 10-gal portable eyewash
Respirator sanitizing equipment
First Aid kit
Drinking water
Gatorade or similar drink
Type ABC fire extinguishers
Half-face and full-face respirators (NIOSH/MSHA approved)
Organic vapor cartridges
OVA and calibration kit
Garden sprayer
Compressed gas horn
Duct tape

4.6 ACCIDENT PREVENTION

On a day-to-day basis, all personnel should be constantly alert for indicators of potentially hazardous situations and for signs and symptoms in themselves and others that warn of hazardous conditions and exposures. Rapid recognition of dangerous situations can avert an emergency. Before daily work assignments, regular meetings will be held, with discussion on:

- Tasks to be performed
- Time constraints (e.g., rest breaks, cartridge changes)
- Hazards that may be encountered, including their effects, how to recognize symptoms or monitor them, concentration limits, or other danger signals
- Emergency procedures

4.6.1 Heavy Equipment Operation

Prior to any drilling activity, efforts will be made to determine whether underground installations will be encountered and, if so, where these installations are located. Hard hats and safety boots, at a minimum, must be worn within 50 feet of the drill rig. The drilling rig cannot be operated within 20 feet of power lines. The FTL or SSO will provide constant onsite supervision of the drilling subcontractor to ensure that all health and safety requirements are being met. If deficiencies are noted, work will be stopped and corrective action will be taken (e.g., retrain, purchase additional safety equipment). Reports of health and safety deficiencies and the corrective action taken will be forwarded to the PM.

4.6.2 Sampling Practices

For all sampling activities, the following standard safety procedures shall be employed:

- All sampling equipment should be cleaned before proceeding to the site.
- At the sampling site, sampling equipment should be cleaned after each use.

- Work in "cleaner" areas should be conducted first where practical.

- The minimum number of personnel necessary to achieve the objectives shall be within 25 feet of the drilling, or sampling activity.

- If emergency and backup subcontracted personnel are at the site, they should remain 25 feet from the drilling, or sampling activity, where practical.

- All unauthorized personnel will remain outside EZ and CRZ at all times.

4.7 SITE SECURITY

Site security is necessary to prevent exposure of unauthorized, unprotected individuals in the work area. Because of the increased hazards from equipment and potential exposures, site security will be enforced by the SSO, who will ensure that only authorized personnel are allowed in the work area and that personnel have the required level of PPE.

4.8 COMMUNICATION

The communication network will be set up to alert site personnel of emergencies and to summon outside emergency assistance, and all site personnel will be trained on the use of the network. Where voice communication is not feasible, an alarm system will be set up to alert employees of emergencies. In some cases, radio communications may be used to communicate with personnel in the EZ. If phone service is not readily available, radios, or portable phones will be used to communicate with outside agencies. Emergency phone numbers and the emergency route to the nearest hospital will be posted in a readily available location and all site personnel will be briefed daily on its location.

4.9 CONTINGENCY PLAN

In the event that an emergency develops on site, the procedures delineated herein are to be immediately followed. Emergency conditions are considered to exist if:

- Any member of the field crew is involved in an accident or experiences any adverse effects or symptoms of exposure while on site.

- A condition is discovered that suggests the existence of a situation more hazardous than anticipated.

4.9.1 Chemical Exposure

If a member of the field crew demonstrates symptoms of chemical exposure of any sort, the procedures outlined below will be followed:

- Another team member (buddy) will remove the individual from the immediate area of contamination. The buddy must advise the FTL of the chemical exposure. The field team will contact the appropriate emergency response agency.

- Precautions will be taken to avoid exposure of other individuals to the chemical.

- If the chemical is on the individual's clothing, the chemical will be neutralized or removed if it is safe to do so.

- If the chemical has contacted the skin, the skin will be washed with copious amounts of water.

- In case of eye contact, an emergency eyewash will be used, washing the eyes for at least 15 minutes.

- As required, the affected person will be conveyed to the nearest hospital emergency room for treatment. The contractor PM will be called immediately, and will assume that contractor's occupational health and safety physician gets in contact with the emergency room to assist in treatment options.

- All chemical exposure incidents must be reported in writing to the Corporate Manager of Health & Safety (CMHS) and Corporate Director of Human Resources (CDHR). The SSO or FTL is responsible for completing the accident report form.

- Immediate follow-up action will be taken to correct the situation which caused the exposure.

4.9.2 Personal Injury

In case of personal injury at the site, the following procedures will be followed:

- Another team member (buddy) will signal the field team leader that an injury has occurred.

- A field team member trained in first aid can administer treatment to an injured worker.

- The victim will then be transported to the nearest hospital or medical center. If necessary, an ambulance will be called to transport the victim. Contractor offices will be immediately contacted to activate contractor's occupational health and safety physician. The physician will contact the emergency room to assist in treatment as necessary.

- The FTL or SSO is responsible for making certain that an accident report form is completed. This form is to be submitted to the contractor CMHS & CDHR by fax or as soon as possible. Immediate follow-up action must be taken to correct the situation that caused the accident.

4.9.3 Evacuation Procedures

- The FTL will initiate the evacuation procedure by signaling the team to leave the site with three blasts of the air horn.

- All personnel in the work area will evacuate the area and meet in the common designated area.

- All personnel suspected to be in or near the contract work area must be accounted for and the whereabouts of missing persons determined immediately.

- Further instructions will then be given by the FTL.

Procedures implemented in the event of a major fire, explosion, or onsite health emergency crisis:

- A field team member will notify the paramedics and/or fire department, as necessary.
- The FTL will signal the evacuation procedure previously outlined and implement the entire procedure.
- The area will be isolated.
- Field team members will be instructed to stay upwind of any fire.
- The area surrounding the problem source will be kept clear after the incident occurs.

4.10 DECONTAMINATION PROCEDURES

If the vapor readings indicate respirator use, the following steps will be followed whenever personnel leave the exclusion zone/work area:

1. Remove all equipment, sample containers, and notes to the CRZ. Obtain decontamination solutions and decon the shovels, auger flights, etc. by brushing them under a water rinse. A high-pressure steam cleaner may also be used for decon. All waste and spent decon solutions will be properly contained.
2. Scrub boots and gloves with a stiff bristle brush and water. Washtubs and chairs will be provided.
3. Remove outer gloves (and boot covers, if used).
4. Remove Tyvek coverall; discard in provided container.

5. Remove hard hat and eye protection.

6. Remove respirator.

7. Remove inner gloves.

8. Wash hands and face.

The decontamination area will be covered with plastic sheeting which will be replaced when torn or heavily soiled, and at the end of each shift.

Each worker will be responsible for cleaning, sanitizing and storing their own respirator in accordance with manufacturer's guidance (i.e., washing in warm water and detergent or sanitizing solution, air drying, and storing in a plastic storage bag). Cartridges will be changed as soon as breakthrough occurs (detection of organic vapor odor while wearing the respirator) and at the end of each shift. Respirators will be kept in storage bags or boxes when not in use.

All spent decontamination fluids (rinse waters, etc.) shall be handled as hazardous waste until lab results indicate otherwise. Fluids shall be placed in proper containers, such as drums, and worked and labeled in accordance with 49 CFR 172.

4.10.1 Decontamination-Medical Emergencies

In the event of physical injury or other serious medical concerns, immediate first-aid is to be administered in lieu of further decontamination efforts.

4.10.2 Decontamination Of Tools

When all work activities have been completed, contaminated tools will be totally decontaminated. It is expected that all tools will be constructed of non-porous, non-absorbent materials. This will aid the decontamination process. Any tool, or part of a tool, which is made of a porous/absorbent material will be discarded and disposed of as a hazardous waste if it cannot be properly decontaminated.

Tools will be placed on a decontamination pad or into a bucket and thoroughly washed using a soap solution and brushing, followed by a fresh water rinse. All visible particles are to be removed before the tool is considered clean.

Those tools which would be damaged by a high pressure spray will be cleaned manually, using a soap solution and mechanical brush, followed by a fresh water rinse.

4.10.3 Heavy Equipment Decontamination

At locations where it is likely that heavy equipment will come in contact with contaminated soil, such heavy equipment will be decontaminated upon leaving the exclusion zone. This is generally not necessary when drilling through concrete or other "clean" pavement.

Partial decontamination efforts will be conducted in the exclusion zone. As much mud, dirt, rocks, etc., as possible will be mechanically removed from the tires, tracks, or outside of the equipment.

The heavy equipment will then be driven onto a decontamination pad located adjacent to the exclusion zone if lab results indicate otherwise. Fluids shall be placed in proper containers, such as drums, and worked and labeled in accordance with 49 CFR 172.

Following the washing, the heavy equipment will be driven into the support zone. Under no circumstances should heavy equipment be allowed to leave the site if it is not decontaminated.

4.11 PLACES OF REFUGE

The SSO will designate the assembly area prior to the start of work, and will include emergency information in the daily "tailgate" briefing. In the event of a site emergency requiring evacuation, all personnel will evacuate to a predesignated area located in the support zone, a safe distance from the exclusion zone boundary ("hot lines"). The SSO will designate the assembly area prior to the start of work and will include emergency information in the daily "tailgate" briefing.

4.12 FIRE

Whenever the possibility of a fire or explosion exists which could affect field investigation personnel or adjacent work area personnel, or which could occur as the result of the investigation, an emergency action plan is prepared as part of the task specification. The emergency action plan includes the following:

- Training is provided to employees by the SSO, including how and when to use the equipment, and evacuation drills; and

- The primary and alternate evacuation routes and places of assembly are posted at the investigation site.

Contractors and subcontractors must conform with the emergency action plan and are trained accordingly.

To protect against fires, the following special precautions must be taken:

- Before any flame-producing devices, i.e., cutting torches or welding irons, are used in the exclusion zone, the SSO must be contacted. A detailed inspection of the work area will be conducted to determine if potential fire sources exist. The fire sources must be removed to at least 35 feet away before work can commence;

- Two full 20-Pound ABC fire extinguishers must be located at the work area when cutting/welding is being conducted; and

- Upon completion of the cutting/welding activities the area will be inspected for hot metal, slag, etc.

Type ABC fire extinguishers will be available onsite to contain and extinguish small fires. The local fire department should be summoned in the event of any fire on site.

4.13 SAFETY EYEWASH

A 10-gallon, 15-minute safety eyewash or small, portable eyewash bottles will be available at the site for the sole purpose of flushing foreign particles or contaminants out of eyes. The SSO will demonstrate the proper operation of the unit prior to the start of work.

4.14 ACCIDENT/INCIDENT REPORT

In the event of an injury or illness, work is to be stopped until the SSO and the CMHS have determined the cause of the incident and have taken the appropriate action. Any injury or illness, regardless of severity, is to be reported, and an accident report form must be filled out and forwarded to contractor's corporate headquarters as soon as possible.

4.15 OPERATION SHUTDOWN

Under certain extreme hazardous situations the onsite personnel, SSO or SSR may request that operations be temporarily suspended while the underlying hazard is corrected or controlled. During operation shutdown, all personnel will be required to stand upwind to prevent exposure to fugitive emissions. The SSO will have ultimate authority for operations shutdown and restart.

4.16 SPILL OR HAZARDOUS MATERIALS RELEASE

Small spills will be immediately reported to the SSO and dealt with according to chemical manufacturers' recommended procedures. Spills or release of hazardous materials which result in human exposure or offsite environmental contamination will be promptly reported by the SSO to the proper authorities and appropriate measures taken to contain and/or collect the material for approved storage and disposal.

4.17 COMMUNITY SAFETY

There is a low potential for migration of chemicals from the site other than through groundwater or air emissions, both of which would be expected to contain low concentrations of hazardous material. In the unlikely event that significant offsite release of contaminants occur during the course of the field work, the appropriate state and local authorities will be notified immediately

and appropriate actions will be taken to protect the public health and mitigate the contaminant release.

4.18 TRAINING AND MEDICAL SURVEILLANCE

All contractor site personnel and subcontractor's personnel will have met the requirements of 29 CFR 1910.120 (e), including 40 hour training or its recognized equivalent annual refresher training and supervisor training. All contractor site personnel and subcontractor's personnel are participating in medical surveillance programs that meet the requirements of 29 CFR 1910.120(f). The PM will maintain current copies of training certificates and statements of medical program participation for all site personnel at the site.

In addition, all contractor site personnel and subcontractor personnel will sign a copy of the Safety Plan Acceptance Agreement Form. The PM will maintain these agreements at the site, and forward them to the CMHS at the conclusion of the operation.

Prior to the start of operations at the site, the SSO will conduct a tailgate safety meeting, which will include all personnel involved at the site. At this meeting, the SSO will discuss:

- General contents of this HASP;
- Types of hazards at the site and means for minimizing exposure to them;
- The type of monitoring that will be performed;
- PPE that will be used;
- Location and use of emergency equipment; and
- Emergency evacuation signals and procedures.

Subsequent site safety briefings will be conducted prior to each shift to review pertinent safety issues, discuss any problems, and outline safety aspects of the shift's tasks.

4.19 RECORDKEEPING

The PM and SSO are responsible for site recordkeeping. Prior to the start of work, they will review this plan; if there are no changes to be made, they will approve the plan.

All contractor and subcontractor's personnel will review the HASP and sign the Safety Plan Acceptance Agreement Form; copies of these forms will be forwarded to the CMHS.

The SSO will conduct a "tailgate" Site Safety Briefing prior to each shift (usually the first onsite activity of the morning) and all attendees and briefing subjects will be listed in the field log book. Copies will be available to the CMHS.

Any accident or exposure incident will be investigated and a report prepared and forwarded to the office administrative manager , the CMHS, and the CDHR.

All instrument readings and calibrations, PPE use and changes, health and safety-related issues, and deviations from or problems with this HASP will be recorded in the SSO's field notebook. As required, all portions of the SSO's field notebook will be available to the CMHS for review at the completion of field operations.

SAFETY PLAN ACCEPTANCE AGREEMENT
For
142nd Fighter Group, Oregon Air National Guard
Portland International Airport
Portland, Oregon

I have received a copy of the Health and Safety Plan for the Project. I have reviewed the plan, understand it, and agree to comply with all of its provisions. I understand that I could be prohibited from working on the project for violating any of the health and safety requirements specified in the plan.

SECTION 1.0 INTRODUCTION

This site-specific Quality Assurance Project Plan (QAPP) presents the overall policies, data quality objectives, and specific quality assurance and quality control requirements that the subcontractor will employ during the field effort for the Remedial Investigation at the 142nd Fighter Group (FG), Oregon Air National Guard (OANG), Portland International Airport, Portland, Oregon.

The overall objective of the QAPP is to establish guidelines for field sampling, documentation, laboratory analysis, over-all quality assurance and quality control procedures, and reporting requirements that will result in data of known quality. Specific procedures for field activities are located in Appendix C, Standard Operating Procedures (SOPs). The QAPP presents qualitative and quantitative goals for precision, accuracy, representativeness, comparability, completeness, and sensitivity (PARCCS) to ensure that the data will met the needs of the end user.

The specific objectives of the field effort are:

- To confirm or deny the existence of potential contaminants identified during the Preliminary Assessment (PA) and Site Investigation (SI) at Installation Restoration Program (IRP) Site Nos. 1, 2, 3, 4, 5 and 7.

- To confirm or deny the existence of potential contaminants identified in limited site-specific sampling efforts outside the scope of the SI at Site No. 9 and No. 10 and visual observations at Site No. 11 and to identify any additional contamination.

- To delineate, vertically and horizontally, the areas of contamination identified during previous investigations.

- Establish background conditions for soil and groundwater media to compare SI and Remedial Investigation (RI) sample results against the background data for selection of remedial alternatives for sites requiring remedial action.

- To locate and identify any buried material contained in the landfill at Site No. 8.

- To provide high quality field analytical data to make decisions on further action required in the field on a real time basis and supply supporting fixed-base laboratory analysis necessary to prepare a comprehensive investigative report.

The scope of field sampling and analysis to be performed at all Sites is discussed in Section 6.0 of the Work Plan. Sampling for all primary points will consist of site specific contaminants of concern. Secondary sampling point analyses will consist exclusively of parameters that include detected compounds found in primary analysis. Field and confirmatory sample analysis and sample quantities are presented in Table 1.1.

MCAWW, Methods for Chemical Analysis of Water and Wastes (MCAWW).
*MAX/MIN number of samples
**PPM Metals will be analyzed for both total and dissolved metals for all but 7 samples.
***Field parameters will be based on USEPA approved methods listed but will not adhere to definative level data analysis requirements. Soil extraction will be required for all soil/sediment samples.
Numbers reflect sampling points.
Actual number of analysis will be 169/377.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 2.0 ORGANIZATION AND RESPONSIBILITIES

2.1 ORGANIZATION

The subcontractor will conduct an RI at IRP Site Nos. 1, 2, 3, 4, 5, 7, 8, 9, 10, 11 and background sampling to delineate suspected or identified areas of contamination and identify any additional contamination at OANG, Portland International Airport, Portland, Oregon. This work will be performed under the direction of the Hazardous Waste Remedial Actions Program (HAZWRAP). The project management organization is shown in Figure 2.1.

2.2 AUTHORITY AND RESPONSIBILITY

2.2.1 Hazardous Waste Remedial Actions Program (HAZWRAP)

HAZWRAP is responsible for providing direct technical oversight and direction to the subcontractor during all tasks performed on this project. HAZWRAP has the contract management responsibilities; all technical direction to the subcontractor must be initiated through HAZWRAP representatives. HAZWRAP staff will provide assistance and information to the subcontractor regarding appropriate permits, badges, security information, access, waste-handling practices, etc. HAZWRAP will provide on-site technical direction and guidance as needed during the RI field effort. The HAZWRAP Project Manager is the principal point of contact with the OANG and is responsible for implementation of the technical requirements and the statement of work (SOW).

2.2.2 Headquarters Air National Guard Installation Restoration Program (IRP) Coordinator

The Headquarters Air National Guard (HQ ANG/CEVR) Installation Restoration Program (IRP) Coordinator is responsible for the implementation of the IRP and related activities at the Base, including technical and contractual direction of activities performed at the site through HAZWRAP.

2.2.3 Subcontractor

The subcontractor is responsible for all activities involved in conducting the RI. The subcontractor is responsible for day-to-day execution of the project, programmatic decisions,

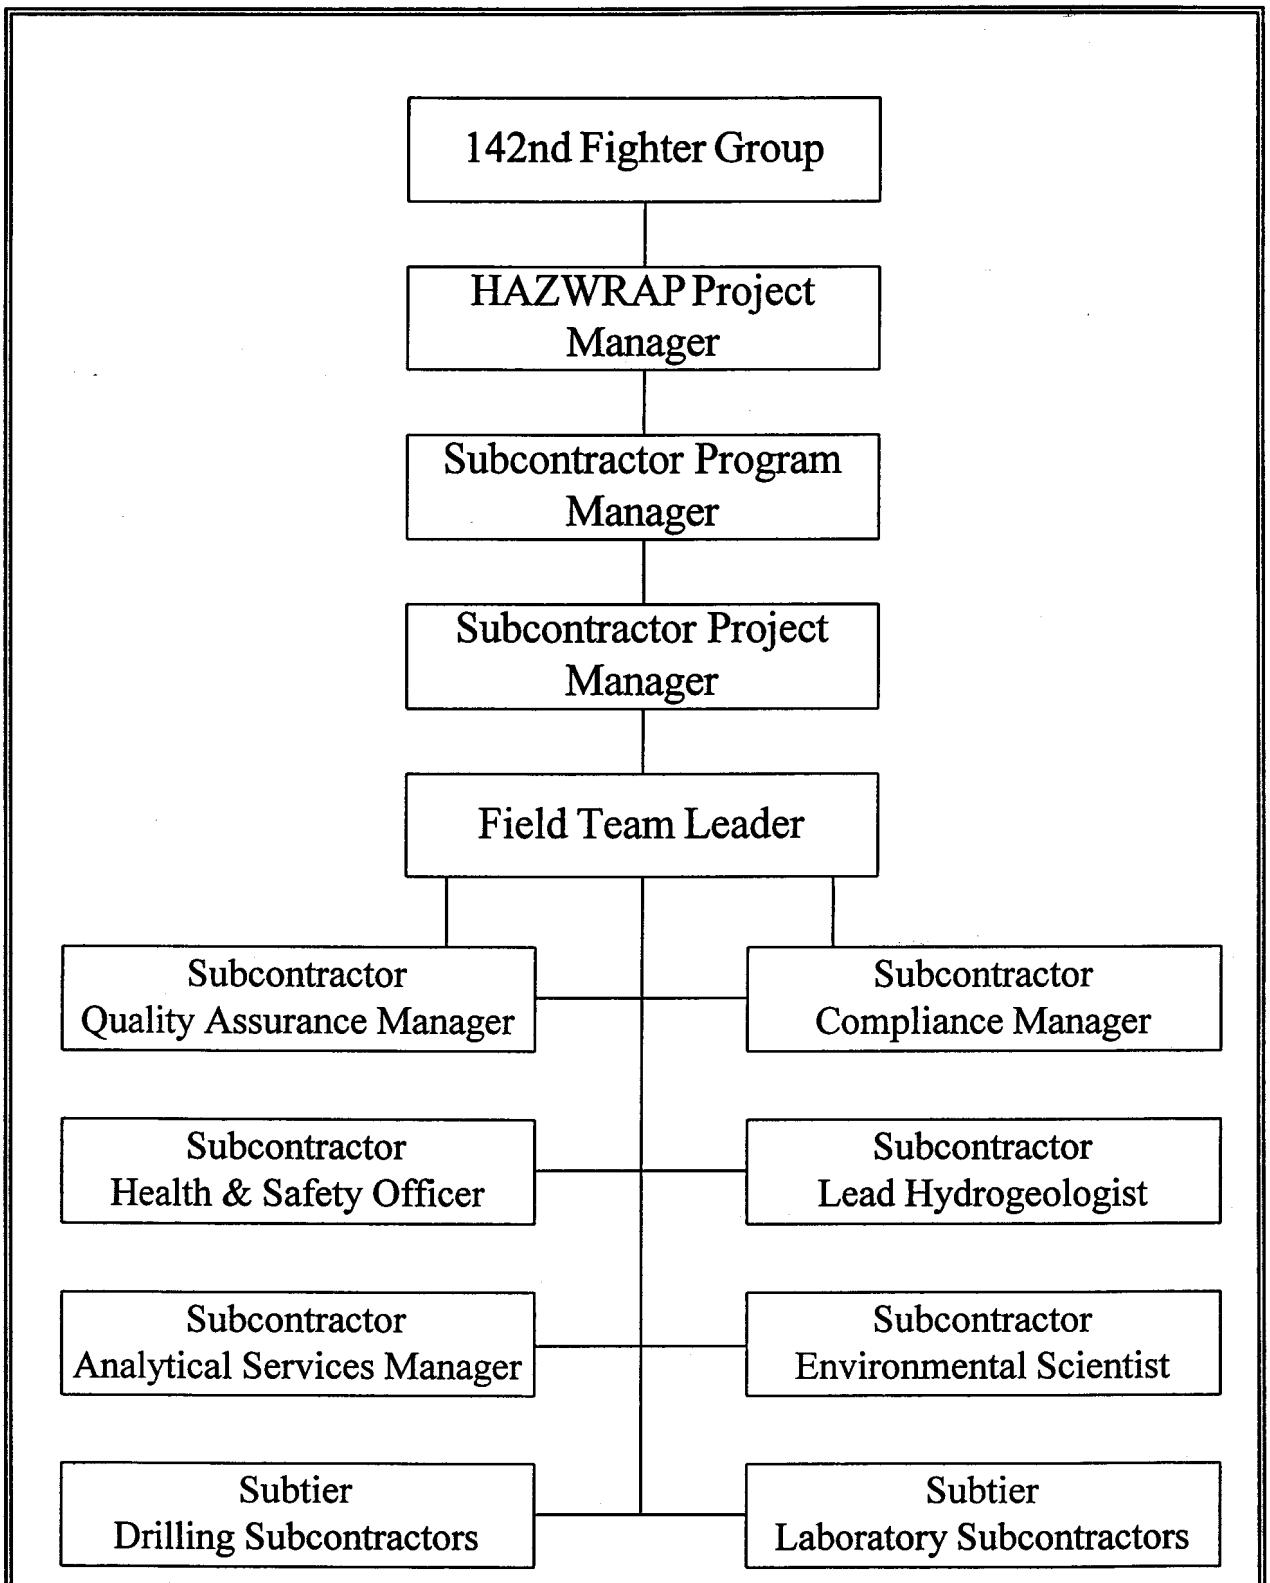

Figure 2.1	**Project Organization Chart** 142nd Fighter Group, Oregon Air National Guard Portland International Airport, Portland, Oregon	OPTECH Operational Technologies CORPORATION

meeting milestones, and transmitting deliverables. The project team will include the following key personnel:

The Program Manager will be responsible for the overall execution of this project, for contract negotiation or modification, for organizational coordination, and for maintaining an open line of communication with the HAZWRAP Project Manager.

The Project Manager (PM) will directly supervise the project team, direct field operations, and coordinate subcontractor and sub-tier contractor support. The Project Manager will be the technical interface between HAZWRAP and the project team.

The Quality Assurance/Quality Control (QA/QC) Manager will be responsible for ensuring that effective procedures and controls are implemented to achieve a high level of project accuracy. Details of the QA/QC Manager's duties are provided in other sections of this QAPP.

The Site Safety Officer (SSO) will be responsible for assuring that threats from physical and chemical hazards are mitigated through effective execution of the Health and Safety Plan.

The Data Management and Analytical Evaluation Manager (DEM) is responsible for all subcontracted laboratory performance including data management, reviewing analytical data from field and fixed-base laboratories, and determining compliance with appropriate analytical QA/QC requirements, data quality objectives (DQOs) and turn-around time requirements. The verification process is performed independently of the laboratory program to assist in determining whether the data meets the DQOs.

The Field Team Leader is responsible for direct supervision of all field operations including planning, conducting, and overseeing all field personnel, including sub-tier contractors.

2.2.4 Sub-Tier Contractor Requirements

The subcontractor is responsible for the cost, schedule, and quality of all work performed under this contract delivery order, including the work of sub-tier contractors. The subcontractor will hire sub-tier contractors to provide services in any area where support to

subcontractor efforts is required. Subcontractor's Project Manager will maintain oversight of the sub-tier contractors' completion of specified tasks with respect to technical performance, quality, and adherence to cost and schedule. All sub-tier contractor activity will adhere to applicable site procedures, policies, and the project QAPP. This requirement will be included in all contracts between the subcontractor and sub-tier contractor. Failure of a sub-tier contractor to comply with requirements of the QAPP, or other contractual requirements, may be viewed as a breach of contract and grounds for contract termination.

Procurement of laboratory sub-tier contractors for analyzing environmental samples shall be strictly controlled. Only fixed-base laboratories recommended by HAZWRAP which have a demonstrated capability to provide the level of data quality required for this project will be employed. Field laboratories will be required to undergo extensive performance based review and surveillance. All subcontracted laboratories must comply with all requirements presented in the Work Plan, HAZWRAP Requirements for Quality Control of Analytical Data (DOE/HWP-65/R1, June 1990) and Quality Control Requirements for Field Methods (DOE/HWP-69/R1, June 1990). Minimum elements of analytical services procurement criteria shall include the following:

- Demonstrated ability to perform the analyses required at a specific capacity;
- Ability to handle the types of material to be analyzed, including all applicable licenses and permits;
- Demonstrated ability to perform the types of analysis and QC required.
- Demonstrated ability to produce documentation and deliverables required for this project including analytical results, electronic data, and mapping information in a timely manner.
- Capable and available laboratory equipment and personnel; and
- The field laboratory will have the ability to incorporate site-specific requirements of this QAPP into a Site specific laboratory quality assurance plan and Standard Operating Procedures (SOPs) for the field laboratory.

SECTION 3.0 DATA QUALITY OBJECTIVES

DQOs are quantitative and qualitative statements specified to ensure that data of known and appropriate quality are obtained during the RI activities. To ensure that data generated during field activities are adequate to support decisions regarding the selection of appropriate corrective measures, the objectives and the method by which decisions will be made must be established in the project planning process. DQOs are based on the specific use of the data collected. Data obtained during this RI will provide the basis for decisions on corrective measures to ensure sites are within compliance standards. Specifically, the data collected during this investigation will be used to:

- Characterize sources of contamination and pathways.
- Determine the nature and extent of contamination.
- Perform a screening risk assessment.
- Make recommendations for additional investigation, remedial actions, or decision documents.

The quantitative measurements that estimate the true value or actual concentration of a physical property always involve some level of uncertainty. The uncertainty associated with a sample generally results from: (1) natural variability (heterogeneity) of the sample, (2) sample handling operations and conditions, (3) spatial and temporal patterns, and (4) analytical variability. These uncertainties must be estimated in order to obtain reliable data and to make appropriate decisions about remediation alternatives. If the level of uncertainty can be quantified, then it can be compared to standard quantitative indicators, the DQOs, for data quality. By quantifying the level of uncertainty a decision maker will be able to use the results derived from the data collected.

3.1 QUALITY MANAGEMENT

Subcontractor has overall responsibility for QA activities during this project. The QA/QC Manager or a designee will be responsible for ensuring all QC procedures are followed. The QA/QC Manager or his/her designee will be responsible for conducting audits to verify that the QA Program is implemented in compliance with project-specific requirements and United States Environmental Protection Agency (USEPA) regulations. Immediate corrective actions will be taken at any time it is deemed necessary, and verification of corrective actions shall be provided. All quality control procedures will be performed in accordance with this QAPP.

3.2 DATA QUALITY OBJECTIVE LEVELS

DQOs are divided into two data quality levels. These levels express the uncertainty level a decision maker is willing to accept in results derived from environmental data. As such, they are a management tool used to decrease the probability that data will lead to an incorrect conclusion.

Two levels of data options to support data collection are identified by USEPA. These QC Levels are definitive and screening level data as described in EPA/504/G-93/71. These levels are based on the level of accuracy and precision required, and the intended use of the data. HAZWRAP analytical QC Levels A and B correspond to screening level data. HAZWRAP analytical QC levels C and D correspond to definitive level data.

3.2.1 Screening Level Data

Screening level data is generated by rapid, less precise methods of analysis with less rigorous sample preparation. Sample preparation steps may be restricted to simple procedures such as dilution with a solvent, instead of elaborate extraction/digestion and cleanup or direct matrix introduction. Screening data provide analyte identification and potentially supply limited quantitation, although the quantitation may be relatively imprecise.

This level is characterized by the use of hand-held instruments that may identify the presence of a class of compounds, without actually identifying or quantifying a specific compound. This level of data may be used for (1) delineation of contaminated zones, (2) gross determination of analytes in samples or (3) health and safety screening.

Field grade analytical instruments that allow identification of compounds and, in some instances, quantification with moderate accuracy and precision limits are also considered to produce field screening data. Normally field grade analytical instruments are used in a mobile or temporary laboratory on site. For the field effort at the 142nd FG, two tiers of screening level data will be required: (1) field measurement data, and (2) field analytical screening data.

For the field effort, field measurement data that are not confirmed by definitive level data are specified for the following activities:

- Health and Safety Monitoring - Health and safety monitoring will be performed with portable hand-held instruments and colorimetric response tubes. The intended use of the data is to identify the presence or absence of contaminants during site activities. Since extensive QC is not required for health and safety monitoring, definitive confirmation is not required.

- Field Measurements - Routine field measurements, such as water level measurements, pH, and conductivity measurements may also provide input for site characterization. Definitive confirmation is not required, because the intended use of data is primarily for monitoring. Field measurement data will be acquired in the field for dissolved oxygen (DO) and carbon dioxide, (CO_2), in up to four groundwater samples at each site. Soil gas measurements for oxygen, (O_2), and CO_2 will be performed for up to four points at each site in the field. Approximately four groundwater and four soil samples from each site will be collected and shipped to the fixed-base laboratory for analysis of nitrate, nitrite, ammonia, and phosphorous (total and reactive). The data is designed to meet field measurement data quality objectives but will be analyzed at a fixed base laboratory due to the wide range of parameters, equipment, reagents and man hours required to perform these tests for soil and groundwater in the field. Results only will be reported for the field measurement-type data analyzed at the fixed-base laboratory. No field QC samples, confirmation samples, or laboratory QC samples will be collected or analyzed. These data are for semi-quantitative screening purposes only and will not require definitive confirmation

- Field Screening - Field screening of soil and groundwater samples using a photoionization detector (PID), or an organic vapor analyzer (OVA) provides preliminary qualitative data and help to prioritize samples for further analysis or disposal. These data are for semi-quantitative screening purposes only and will not require definitive confirmation.

In addition to screening level data for field measurements, field analytical data for qualitative and quantitative purposes will be acquired using a field mobile laboratory. The field analytical data collected will be of a high quality screening level intended to be used to make real-time decisions on further actions required. Screening level data will be generated using more analytical QC than the minimum required for HAZWRAP Level B field screening analysis, but will not meet all definitive level data requirements due to modified sample preparation

techniques for semivolatile organic compounds (SVOCs), and the types and frequencies of field and laboratory QC.

- Field Analytical Screening - A mobile laboratory will be capable of generating quantitative and qualitative results for volatile organic compounds (VOCs) and semivolatile organic compounds (SVOCs) utilizing mobile laboratory grade gas chromatography/ mass spectrometry (GC/MS). These data are for both qualitative and quantitative purposes. The data generated for both VOCs and SVOCs will be closely monitored for data quality through tune accuracy, initial and continuing calibrations precision and accuracy, surrogate and internal standard recoveries, and matrix spike/matrix spike duplicate precision and accuracy.

At least 5% of field analytical screening level data (only VOC and SVOC) will be confirmed using analytical methods and QA/QC procedures and criteria associated with definitive data.

3.2.2 Definitive Level Data

Definitive data are generated using rigorous analytical methods, such as approved USEPA reference methods. Data are analyte-specific, with confirmation of analyte identity and concentrations. Methods produce tangible raw data (e.g., chromatograms, spectra, digital values, etc,) in the form of paper printouts or computer-generated electronic files. Data may be generated at the site or at an off-site location, as long as the QA/QC requirements are satisfied.

This level of data analysis is characterized by the fixed-base laboratory analysis or sophisticated mobile laboratories, and provides lower detection limits, a wide range of calibrated analytes, matrix recovery information, laboratory process control information, and known precision and accuracy. USEPA-accepted methods, such as those in Test Methods for Evaluating Solid Waste, Physical/Chemical Methods, SW-846, (SW-846), the National Pollution Discharge Elimination Systems (NPDES), and Contract Laboratory Program (CLP) are utilized for definitive data.

For the field effort at OANG, samples requiring definitive level data analysis will be performed at a HAZWRAP-recommended fixed-base laboratory. All samples requiring analysis for priority pollutant metals (PPMs) (filtered and unfiltered), total petroleum hydrocarbons (TPH), and polychlorinated biphenyls (PCBs) will be submitted to the fixed-base

laboratory. In addition, definitive level data analysis will be performed for approximately five percent of samples that are analyzed by the field laboratory for VOCs and SVOCs. The definitive level data analysis of these samples will serve as a confirmation analysis of the field laboratory results for VOCs and SVOCs.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 4.0 QUALITY CONTROL FOR SAMPLE COLLECTION AND ANALYSIS

The overall quality control objective is to develop and implement procedures that will ensure sufficient quality in field sample collection, field laboratory analysis, fixed-base laboratory analysis, and reporting to meet the needs of end users of the data. Documentation requirements including field logbooks, chain-of-custody forms, and field change order requests are located in other sections of the QAPP. This section presents overall analytical quality control protocols from the time of sample collection through data analysis. DQOs and precision, accuracy, representativeness, completeness, comparability and sensitivity (PARCCS) of the analytical data are discussed in Section 5.

4.1 FIELD QUALITY CONTROL SAMPLES

Field duplicate samples, field blanks, equipment rinseates, and trip blanks will be submitted to the analytical laboratories to provide the means to assess the quality of the data resulting from the field sampling program. Field and trip blanks samples will be analyzed to check for procedural contamination and ambient conditions at the site that may have caused sample contamination. Duplicate samples will be submitted under a non-indicative sample identification to provide a quality assurance check on analytical procedures and results. The QC samples and associated frequencies for this project are described below.

- **Trip Blanks** - Trip blanks are used to detect contamination by VOCs during shipping and handling. Trip blanks are 40-mL volatile organic analysis (VOA) vials of analyte-free water and are preserved with HCL to pH $\leq$ 2. Trip blanks will be supplied by the laboratory performing the analysis. Trip blanks must have zero headspace and should not be opened in the field. One trip blank set will be placed in each cooler containing VOA samples, regardless of sample matrix, and submitted to the fixed-base laboratory. One trip blank will be submitted to the field laboratory per week. The number of VOA vials comprising a trip blank set is laboratory-dependent; the number of vials required will be specified by the selected fixed-base laboratory. Trip blanks are analyzed for VOCs only.

- **Field Blanks** - Field blanks are QA/QC samples intended to determine if any of the water used during the field investigation contains detectable concentrations of any organic or inorganic analytes that may impact the quality of the samples. Field blanks are samples of the source water used for decontamination and steam cleaning.

At a minimum, one sample for each source of water will be collected. Field blanks will be analyzed for the same parameters as the original samples of interest by the fixed-base laboratory. Field blanks will be collected and analyzed at a frequency of 1 per mobilization per source at the field laboratory and 1 per field event (any time frame where sampling has not occurred for more than 24 hours) for fixed laboratory analysis. American Society for Testing Materials (ASTM) Type II water used for final rinsing, and the tap water used for initial cleaning, are sources of water that are commonly sampled.

- **Equipment Rinseates** - Equipment rinseates are used as a measure of the effectiveness of the decontamination process. Equipment rinseates are samples of the final analyte-free water rinse from equipment cleaning and are submitted to the fixed-base laboratory for analysis. The equipment rinseates will be analyzed for the same analytes as the samples that are collected. Samples will be collected for every type or piece of sampling equipment at a frequency of one for every 10 investigative samples collected per sample matrix per site and analyzed at the field laboratory. Equipment rinseates will also be analyzed at a 10% (of the project total equipment rinseates) frequency at the fixed-base laboratory.

- **Field Duplicates** - Field duplicates are used to assess the precision of sampling techniques and to provide checks on laboratory and field procedures. Field duplicates will be collected at a frequency of one for every 10 samples collected per sample matrix for field analysis. Field duplicates will also be collected at 10% frequency for fixed- base confirmation analysis of VOCs and SVOCs (10% duplicates of the 10% confirmation samples). For parameters analyzed only at the fixed-base laboratory, field duplicates will be submitted at a frequency of 10% of total samples collected for each matrix.

- **Matrix Spike/Matrix Spike Duplicate (MS/MSD)** - MS and MSD samples are samples from a specific media that have been spiked at the laboratory with known quantities of analytes. MS and MSDs are used to determine the accuracy and precision of the laboratory analyses as well as matrix interferences. Data from MS and MSD sample recovery supply percentage recovery information so the laboratory can evaluate its measurement accuracy and precision. MS and MSD samples are equal portions of a single initial sample that has been spiked with specific analytes in known quantities and must meet certain laboratory requirements to be acceptable.

The total number of MS/MSD samples will be at a frequency of one per 20 samples collected per sample matrix or every 14 days, which ever is more frequent for fixed-base confirmation analysis and field laboratory analysis.

4.2 CONFIRMATION SAMPLING

Confirmation samples for definitive level data analysis at a fixed-base laboratory, independent of the field laboratory, are used to determine whether the field laboratory is able to accurately and precisely analyze samples to the quality and precision required to meet DQOs. Approximately five percent of samples that are analyzed by the field laboratory for VOCs and SVOCs will be collected in duplicate and submitted to the fixed-base laboratory for VOC and SVOC confirmation analysis. Confirmation samples for fixed-base laboratory analysis of VOCs and SVOCs will be selected at random, but will be evenly distributed among the ten sites. Confirmation samples will include one background monitoring well from each round of sampling and at least three samples reported above the action level by the field laboratory, and three samples reported below the action level (or as non-detects) by the field laboratory.

Sample collection reproducibility, analytical reproducibility, and the acceptable variability of accuracy will affect the range or values when comparing field confirmation data. This variable will consequently be summed to obtain the acceptable window for confirmation.

4.3 ANALYTICAL PARAMETERS

Analysis of soil and groundwater samples taken in accordance with the Field Sampling Plan for the site will be performed in accordance with analytical procedures that conform to USEPA guidelines published in the SW-846 and Methods for Chemical Analysis of Water and Wastes, (MCAWW).

Field laboratory analysis will consist of VOC and SVOC analysis for water and soil samples. The water samples will be analyzed using SW-846 Method 8260 for low level VOC analysis with purge-and-trap sample preparation Method 5030. The USEPA 3/90 Target Compound List (TCL) plus BCM will be reported for soil and water. The TCL with Practical Quantitation Limits (PQLs) for VOCs are shown in Table 4.1. Analysis of soil and water samples in the field for SVOC will use SW-846 Method 8270 with a modified SW-846 Method 3510, separatory funnel extraction for water samples and a modified SW-846 Method 3550, ultrasonic extraction, for soil samples. Modifications to the SVOC method include a micro extraction preparation (approximately 100 milliliters or 5 grams of sample and 5-15 milliliters of solvent), and a increased sample injection volume. Due to the modified

extraction the estimated reporting limits for SVOCs in the field laboratory are expected to be five times the PQLs required in the fixed-base laboratory. The reported quantitation limits will be based on method detection limit (MDL) studies performed in the field. Sample injection volume, extraction time, sample volume, and extract volume may be modified to achieve the reporting limits. USEPA TCL will be reported for SVOC samples. Table 4.2 presents the SVOC TCL and estimated quantitation limits (EQLs) for the field laboratory and PQLs for the fixed-base laboratory.

All fixed-base laboratory analysis for definitive level data will require seven day turn-around for results only. Five percent of VOCs and SVOCs analyzed in the field will be submitted for fixed-base analysis. TPH, PCBs, and PPM will be analyzed at the fixed base laboratory only. TPH will be analyzed for soil samples only. Field parameters analyzed at the fixed-base laboratory (nitrate, nitrite, ammonia, and phosphorus) will require 30 day turn-around time for results only. No additional data package will be required for field parameters analyzed at the field-base laboratory.

Fixed-base VOC analysis will use the same preparation and analysis methods used in the field. Fixed-base laboratory SVOC analysis of soil samples will use the same SW-846 methods used in the field without any sample preparation modifications to the extraction methods. Water samples for SVOC analysis may be extracted using more automated procedures including SW-846 Method 3520, liquid-liquid extraction. TPH will be analyzed using SW-846 modified Method 8015 with purge and trap sample preparation (Method 5030) for gasoline range organics (GRO) for soil samples. Extraction preparation methods for soil samples will be required for diesel range organics (DRO) and jet fuel fractions analysis. Soils will be extracted for DRO and jet fuel analysis utilizing Method 3550, sonication. PQLs for TPH analysis are located in table 4.3. PCBs and PPM metals will be analyzed at the fixed-base laboratory using SW-846 Methods 8080 and 6010/7000 series respectively. Sample preparation for PCB water samples will follow SW-846 Method 3510/3520 and soil samples will follow Method 3540/3550. Table 4.4 lists the PQLs for PCBs. Metals samples will be collected for total and dissolved metals aqueous analysis. Dissolved metals samples will be filtered in the field. If all metals detection limits can be achieved by ICP(with the exception of mercury), ICP will be used exclusively. Mercury analysis will follow cold vapor atomic absorption methods SW-846 Method 7470 for soil samples and 7471 for water samples. Practical Detection Limits (PDLs) for all fixed-base metal parameters are located in Tables 4.5.

All soil samples for the RI will be reported on a dry weight basis. Tables 4.1 through 4.5 list soil quantitation limits on a wet weight basis. Actual quantitation limits will be higher for environmental soil/sediment samples based on the moisture content of each sample.

4.4 SAMPLE COLLECTION, PRESERVATION, AND HOLDING TIMES

Procedures for collecting soil and groundwater samples will follow the RI Work Plan (WP), and will conform to USEPA protocols. The Field Team Leader is responsible for ensuring that samples are collected with properly decontaminated equipment and contained in properly cleaned sample containers. The steps required for sample control and identification, data recording, and chain-of-custody documentation are discussed in Section 6 of the QAPP and SOPs located in Appendix C.

Prior to the beginning of each type of sampling event, the Field Team Leader will meet with the assigned sampling personnel and review the purpose and objectives of the event. This meeting will provide final clarification of the sampling event details. Topics of review and discussion will include items such as sampling locations, types of samples to be collected, number of samples to be collected, sample numbering, parameter(s) to be analyzed, sampling procedures, equipment decontamination procedures, and chain-of-custody requirements.

Equipment decontamination is an integral part of the data collection and quality assurance process. The implementation of proper decontamination practices and procedures will begin in the field prior to the use of sample collection equipment. All field sampling equipment will be decontaminated before use and after each sample location, in accordance with SOP No. 7 located in Appendix C.

Sample containers and preservatives used to collect and contain samples designated for chemical analysis generally will be provided by the laboratory performing the analysis. The preferred container types will be I Chem Series 300 Bottles or equivalent. The bottles must be pre-cleaned and traceable to the laboratory that performed the cleaning. The lot number of the containers and reagents used for preservatives must be traceable to the laboratory (or supplier) that performed the initial assay. Certificates of cleanliness must be provided by the laboratory (or supplier) and kept in the project file.

All samples for chemical analysis will be placed on ice as soon as possible following collection. All samples will be chilled to 4°C ± 2°C and maintained at that temperature through transport and subsequent storage at the analytical laboratory. This applies to all samples with exception of aqueous metal samples. In no case will samples be retained over 48 hours on site. Holding times, sample volumes and preservative requirements for fixed-base and field laboratories are shown in Tables 4.6A and B. Samples analyzed by the field laboratory will not require acid preservation but will be maintained at 4°C.

Table 4.6A
Fixed-Base Laboratory Volumes, Containers, Preservation, and Holding Summary of Samples
142nd Fighter Group OANG
Portland International Airport, Portland, Oregon

Parameter	Matrix	Holding Time (from time of collection)	Container	Preservative	Minimum Sample Size
Volatile organics SW-846 Method 8260	Water	14 d	Three 40-mL vials with Teflon-lined caps, brass or Teflon core tube sealed on both ends	4°C , HCl to pH < 2	40 mL
	Soil			4°C	10 g

SECTION 5.0 PRECISION, ACCURACY, REPRESENTATIVENESS, COMPARABILITY, COMPLETENESS, AND SENSITIVITY OBJECTIVES

This section presents general objectives for the level of quality control expressed as PARRCS for the analytical data. The accuracy, precision, and sensitivity of laboratory analytical data must satisfy the quality control acceptance criteria of the analytical protocols for approved USEPA methods in the fixed-base laboratory and project specific requirements for the field laboratory.

5.1 QUALITY ASSURANCE OBJECTIVE FOR ACCURACY

Accuracy is defined as the degree of difference between measured or calculated values and the true value. The closer the numerical value of the measurement comes to the true value, or actual concentration, the more accurate the measurement. Analytical accuracy is expressed as the percent recovery of a compound or element that has been added to the environmental sample at a known concentration before analysis. The following equation is used to calculate percent recovery:

$$Accuracy = Percent\ recovery = \frac{A_r - A_o}{A_f} \times 100\ percent$$

Where:

A_r = Total amount detected in spiked sample
A_o = Amount detected in unspiked sample
A_f = Amount of spike added to sample

5.1.1 Organic Analysis Accuracy

Analytical accuracy will be ensured by performing all method specified and project modified quality control steps. Surrogate recoveries will be monitored for method compliance for all analysis in the field and fixed-base laboratory with the exception of TPH. Table 5.1 lists the surrogate recovery acceptance criteria for all organic parameters requiring surrogate additions (VOC, SVOC, and PCB) .

Table 5.1
Field and Fixed-Base Laboratory Objectives for Accuracy of Surrogate Spike Analysis
142nd Fighter Group, OANG,
Portland International Airport, Portland, Oregon

Fraction	Surrogate Compound	Water % Recovery Limits	Low/Med Soil % Recovery Limits
VOA	4-Bromofluorobenzene	86-115	74-121
VOA	Dibromofluoromethane	86-118	80-120
VOA	Toluene-d_8	88-110	81-117
SVOA	Nitrobenzene-d_5	35-114	23-120
SVOA	2-Fluorobiphenyl	43-116	30-115
SVOA	p-Terphenyl-d_{14}	33-141	18-137
SVOA	Phenol-d_5	10-110	24-113
SVOA	2-Fluorophenol	21-110	25-121
SVOA	2,4,6-Tribromophenol	10-123	19-122
PCB	Decachlorobiphenyl	60-150	60-150

VOA = Volatile Organic Analysis.
SVOA = Semivolatile Organic Analysis, SOW 3-90.
PCB = Polychlorinated Biphenyl.
Note: These limits are for advisory purposes only. They are not used to determine if a sample should be reanalyzed.
Source: USEPA, 1986.

Analytical accuracy will be ensured by performing all method specified and project modified quality control steps. Surrogate recoveries will be monitored for method compliance for all analysis in the fixed-base laboratory with the exception of TPH. Table 5.1 lists the surrogate recovery acceptance criteria for all organic parameters requiring surrogate additions (VOCs, SVOCs and PCBs) .

In addition to surrogate recoveries, fixed base laboratory accuracy for VOC, SVOC and TPH analysis will be evaluated by analyzing a matrix spike/matrix spike duplicate (MS/MSD) sample at a minimum frequency of 1 per 20 samples of similar matrix or every 14 days which ever is more frequent. Table 5.2 lists spike compounds and recovery criteria for MS/MSD samples in the fixed-base laboratory for SVOCs and VOCs. TPH advisory limits will be established by the fixed-base laboratory through the use of control charting.

The general objective for analytical accuracy for organic analysis is to meet 90% of all surrogate compound recoveries (Table 5.1) and MS/MSD recoveries (Table 5.2).

5.1.2 Inorganic Analysis Accuracy

Metals accuracy will be monitored by analyzing a matrix spike sample and a LCS with every sample delivery group. The matrix spike recoveries should not exceed 75-125% for any metal analyzed and LCS recoveries should not exceed 80-120%. The overall goal for inorganic analytical accuracy is to meet 90% of all matrix spike, and LCS recoveries.

5.2 QUALITY ASSURANCE OBJECTIVE FOR PRECISION

Precision is defined as the reproducibility, or degree of agreement, among duplicated (collocated) sample measurements of the same quantity. The closer the numerical values of the measurements come to each other, the more precise the measurement is. Analytical precision is expressed as a percentage of the difference between results of duplicate samples for a given compound. Relative percent difference (RPD) is calculated as:

$$RPD = \frac{|C_1 - C_2|}{\left(\frac{C_1 + C_2}{2}\right)} \times 100$$

Table 5.2
Quality Assurance Objectives for Field and Fixed-Base Laboratory
Accuracy and Precision of Matrix Spike/Matrix Spike Duplicate Analysis
142nd Fighter Group, OANG,
Portland International Airport, Portland, Oregon

Fraction	Matrix Spike Compound	Water		Soil	
		RPD	Percent Recovery Limits	RPD	Recovery Limits
VOA	1,1-Dichloroethene	19	60-136	22	59-172

SVOA	4-Nitrophenol	50	10-80	50	11-114
SVOA	Pentachlorophenol	50	9-103	47	17-109
SVOA	Phenol	42	12-110	35	26-90

Fractions: VOA = Volatile Organic Analysis.
SVOA = Semi-Volatile Organic Analysis.
PCB= Polychlorinated biphenyls

RPD = Relative Percent Difference.

Source: USEPA, 1986.

Where

C_1 = Concentration of the compound in the sample

C_2 = Concentration of the compound in the duplicate/replicate

Sample collection precision will be measured in the laboratory by the analysis of field duplicate samples. Sample collection precision criteria will be twice the analytical precision criteria.

The overall goal for precision is for 90 percent of all data generated by laboratory methods to be within required or method-recommended control limits.

5.2.1 Organic Analysis Precision

Precision of field and fixed-base laboratory VOC, and SVOC analysis will be monitored using MS/MSD RPD values (Table 5.2) . TPH precision will be monitored using matrix spike and matrix spike duplicate analysis of a fuel standard. The advisory precision limits should not exceed 15% RPD for TPH. PCB precision will be monitored using the RPD of the initial calibration and calibration verification response of decachlorobiphenyl (DCB). The RPD of DCB should not exceed 25%.

5.2.2 Inorganic Analysis Precision

Metals precision is assessed using an environmental sample analyzed in duplicate with every sample delivery group. The relative percent difference should not exceed 20% for water samples or 35% for soil samples with duplicate sample values greater than or equal to 5X PDL. A control limit of ± PDL is used if either the sample or duplicate value is <5X PDL.

5.3 QUALITY ASSURANCE OBJECTIVES FOR SENSITIVITY

Sensitivity is the limits of detection for instrumental and chemical analysis. The achievement of method detection limits depends partially on instrument sensitivity to ensure the data quality through constant instrument performance. Quantitation limits for trace metals, PCBs, SVOCs, VOCs, and TPH are listed in Tables 4.1 through 4.5 for field and fixed-base laboratory analysis. All soil/sediment samples will be reported on a dry weight basis. The quantitation limits presented in Tables 4.1 through 4.5 for soils/sediments will be adjusted based on the moisture content of each sample.

5.4 QUALITY ASSURANCE OBJECTIVES FOR COMPLETENESS, REPRESENTATIVENESS, AND COMPARABILITY

Completeness is defined as the amount of valid (useable) data obtained compared to the planned amount and is expressed as a percentage of measurements judged to be valid. The percent of completeness for analytical data can be expressed by the following formula:

$$Completeness = \frac{Number\ of\ useable\ valid\ data\ points\ reported}{Total\ number\ of\ analytes\ for\ each\ parameter\ analyzed} \times 100$$

The completeness goal for the fixed-base and field analysis is 90%.

Representativeness expresses the degree to which data accurately and precisely represents a characteristic of a population, parameter variations at a sampling point, a process condition, or an environmental condition. Representativeness is a qualitative parameter dependent on the proper design of the sampling program and proper laboratory protocol. The sampling networks all designed to provide data representative of facility conditions. During development of these networks, consideration was given to past waste disposal practices, existing analytical data, physical setting and processes. Representativeness will be ensured by using proper sampling techniques, and using analytical procedures. Representativeness is ensured in the laboratory by proper sample storage, analysis, extraction, and digestion within the proper required holding times, acceptable instrument calibration and operation.

Comparability is a qualitative parameter that expresses the confidence with which one data set can be compared with another, and is limited to the other parameters, because only when precision and accuracy are known, can data be compared with confidence. The extent to which existing and planned analytical data will be comparable depends on the similarity of sampling and analytical methods. The procedures used to obtain the planned analytical data, as documented in the QAPP, are expected to provide comparable data. Field and laboratory procedures greatly affect comparability. To optimize comparability, only specific methods and protocols that have been selected, specified as appropriate, and modified as necessary for the RI will be used. By using consistent sampling and analysis procedures, all data sets will be comparable within a specific site and between sites at the installation to ensure that remedial action decisions and priorities are based on a consistent data base. Comparability will be

further ensured by the analysis of USEPA standard reference materials, establishing that analytical procedures are generating valid data.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 6.0 SAMPLE IDENTIFICATION AND CHAIN-OF-CUSTODY REQUIREMENTS

Sample chain-of-custody (COC) procedures require a written record which documents the possession and handling of the sample from the moment of its collection through its analysis. The record must clearly reflect the movement of the sample through the chain-of-custody to ensure the sample has been positively controlled and has not been tampered with in any way. A sample is judged in positive custody when one of the following criteria has been met:

- The sample is in one's actual physical possession;
- The sample is in one's clear field of view after being in one's physical possession;
- The sample is in one's physical possession and is then locked up in a secure container so that no one can tamper with it; or
- The sample is kept in a secured area that is restricted to authorized personnel only.

6.1 SAMPLE IDENTIFICATION

A standardized numbering system will be used to identify all samples taken from water and soil sampling activities. The numbering system provides a tracking procedure to ensure accurate data retrieval of all samples taken. A listing of the sample identification numbers will be maintained by the field task leader, who will be responsible for enforcing the use of the standardized numbering system during all sampling activities. Sample identification for all samples collected during the RI will follow the following format.

This code consists of 10 alphanumeric characters in four information groups:

- Site designator (two characters)
- Sample type (two characters)
- Sample identifier (four characters)
- Sample sequence qualifier (two characters)

If no information is required for a particular sample, the spaces must be filled with an "X". If only one character is needed in the multi-character fields, the character must be right-justified and the leading spaces filled with an "X".

6.1.1 Site Designator

All samples collected in this field effort will be identified by a 10-character code beginning "OB" which signifies Oregon Base.

6.1.2 Sample Type

The two-character sample type code identifies the general source type and media of the sample. Sample type codes that may be applicable to this field project are as follows:

- BG Background sample;
- DS Soil sample from drum containing cuttings;
- DW Decontamination water;
- EB Equipment blank;
- FB Field blank;
- GS Groundwater grade sample;
- GW Groundwater permanent monitoring well;
- MS Groundwater microwell sample;
- RS Field duplicates;
- SD Sediment;
- SS Surface soil;
- SU Subsurface soil;
- SW Surface water;
- TB Trip blank; and
- VP Groundwater vertical profile sample.

6.1.3 Sample Identifier

The third segment will consist of 4 digits. The first 2 digits will identify the site number. The second 2 will designate the soil boring or monitoring well identification number.

6.1.4 Sample Sequence Qualifier

The last set of two digits will sequentially identify the vertical samples taken from a single location.

6.2 SAMPLE LABELS

All samples will be identified with a label attached directly to the container and bar codes scanned into a sample tracking database. Sample label information will be completed using waterproof black ink and will contain the following information:

- Company name and site;
- Sample number;
- Parameters to be analyzed; and
- Preservative (if any).

Sample bar code information will contain sample identification (ID) only. The data evaluation manager will be responsible for obtaining a copy of the COC and entering collection date, analytical parameters, and location coordinates into the database.

6.3 CHAIN-OF-CUSTODY (COC) RECORD

To maintain a record of sample collection, a COC custody record will be filled out for each sample destined for mobile and fixed-base analysis at each sampling location, for the transfer of samples between sample custodians, shipment, and receipt by the laboratory. A copy of the standard subcontractor's COC record is shown in Figure 6.1. Sample COC procedures require that the possession and handling of the sample from the moment of its collection through analysis be documented by written record. The record must clearly reflect the movement of the sample through the COC to ensure the sample has been positively controlled and has not been tampered with in any way. Each time the samples are transferred, the signatures of the persons relinquishing and receiving the samples, as well as the date and time of transfer, will be documented.

6.4 TRANSFER OF CUSTODY AND SHIPMENT

Prior to the shipment of samples, the COC record will be signed and dated by a member of the field team who has verified that those samples indicated on the COC record are indeed being shipped. After packaging has been completed, the samples will be locked within the cooler, and custody seals, signed and dated by a member of the field team, will be placed over the lid edge for fixed-base laboratory samples. Field laboratory samples will be delivered without custody seals.

SAMPLE CHAIN-OF-CUSTODY FORM (REDUCED)
142nd FG, Portland International Airport
Portland, Oregon

OPTECH OPERATIONAL TECHNOLOGIES CORPORATION

OCTOBER 1995

All samples will be shipped by courier, such as Federal Express, or hand delivered by the subcontractor's personnel to the field analytical laboratory. Confirmation samples will be transported, generally each day, by field personnel from the Base to the courier location for subsequent shipment to the laboratory or hand carried to the mobile laboratory. Upon receipt of the samples at both of the laboratories, the receiver will complete the transfer by dating and signing the COC record. If shipped by commercial courier, the air bill number and shipping data will be transcribed to the chain of custody in the appropriate signature/date block. A copy of the air bill is to be kept with the field copy of the COC form to reflect specific shipping information.

6.5 LABORATORY SAMPLE RECEIVING AND STORAGE

- Upon receipt, the sample custodian will inspect sample containers for integrity. The presence of leaking or broken containers will be noted on the laboratory's Sample Receipt Form. The sample custodian will sign the COC record with the date and time of receipt, thus assuming custody of the samples.

- The information on the COC record will be compared with the information on the sample tags and labels to verify exact sample identity. Any inconsistencies will be immediately resolved with the field sampling representative before sample analysis proceeds.

- Samples will be moved to a locked restricted access sample storage refrigerator maintained at 4°C ± 2°C. The laboratory is required to document all internal custody transfers.

- The laboratory will submit copies of appropriate COCs with each data package and return original COCs at the end of the project.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 7.0 DOCUMENTATION PROCEDURES

Individual logbooks will be bound notebooks with water-resistant or waterproof pages, and sequentially numbered by either mechanical overprint or handwritten entry. All entries will be legible and made with black, waterproof ink. No pages will be removed from a logbook. For any page partially filled with an entry, a line will be drawn diagonally from below the last line entry to the bottom of the page. Blank pages will be identified by writing "page intentionally left blank". Individuals making entries will sign and date the bottom of each page of the respective logbooks. Corrections will be marked through with a single line, initialed, and dated. No "white-out," erasure, or other obliteration will be accepted.

7.1 SITE LOGBOOKS

The Field Team Leader will maintain a Site Logbook which summarizes daily field activities, but does not contain the same level of detail as the field logbook. The Site Logbook will be used to record daily weather conditions, personnel, activities, and references the appropriate field logbooks and data forms for various field activities. It will also be used to record all field changes in scope with supporting rationale.

The following entries, as a minimum, will be included in the Site Logbook:

- Day; date; time arrived on-site; time daily activities completed; weather conditions; names, titles, and organizations of personnel present on-site; and individuals responsible for maintaining respective field logbooks.

- Name, title, and organization of visitors on-site.

- Reference to other logbooks or field data forms maintained for documentation of field activities.

- Brief description of daily site activities, i.e., location, volume, number, amount, etc.

- Records of all custody and transfer details, including air bill numbers, analytical request forms, chain-of-custody forms, sample label numbers, and laboratories to which samples were shipped, or reference to applicable field logbooks containing specific information.

- List of equipment decontaminated, number of decontamination events, and exceptions to approved procedures, if necessary. In lieu of recording this information, specific field logbook(s) documenting these activities will be referenced.

- List of instrument calibrations, calibrating personnel, and page number(s) of the calibration log.

- List of equipment malfunctions or breakdowns occurring along with disposition, i.e., repair, replacement, etc., along with effect on overall project.

- Record of deviations from scope of work plan. If a Field Change Request (FCR) is used, record number; otherwise, record details and effect on overall project.

- Record of all telephone calls relating to field activities.

7.2 FIELD LOGBOOKS

All data collection activities performed at a site will be documented using waterproof, indelible black ink, in a field notebook or on the COC forms. Field notebooks will be bound, waterproof books, and will be assigned to individual field personnel for use during the duration of their field activities. Entries will be as detailed and as descriptive as possible so that a particular situation can be recalled without reliance solely on the sampler's memory. All field log activities will be dated and signed by the person making the entries. If an incorrect entry is made in any type of data document, the incorrect data will be lined out with a single line, the correct information entered, and the correction initialed and dated by the person making the correction. Like original entries, corrections will be made in indelible black ink. At the end of each day, all logbooks may be requested to be turned in to the Field Team Leader so that he may assess the entries for completeness.

The Field Team Leader will designate a member of the field team to photocopy, at the end of each day, all field logs (notebook pages and standard forms) generated during that day. At the completion of a work shift, all field logs, and notebook pages, and standard forms will be entered into the project files. All copies of field logs and standard forms will be transported and stored off-site at the completion of each work shift.

The following entries, as a minimum, will be included in the field logbook:

- Day; date; time arrived on-site; time daily activities completed; weather conditions; and names, titles, and organizations of personnel involved in the task.

- Name, title, and organization of visitors on-site.

- Specific description of all activities in detail, or reference to forms used to record applicable information.

- Specific details of field tests conducted with references to field data forms or other data records completed.

- Volumes of water purged, number of drums filled, etc.

- Specific descriptions of samples collected, listing label numbers, sample containers, and volumes, preservation methods, packaging, chain-of-custody form number(s), and any other pertinent information available.

- List of decontamination events, including personnel, time, equipment, and procedures.

- List of instrument calibrations including a description of any problems encountered.

- List of equipment malfunctions including a brief description of dispositions, i.e., repair or replacement.

7.3 FIELD DATA RECORD FORMS

Data record forms will be used for applicable field activities. These forms will ensure that all required data and observations were recorded in a consistent manner. No blank spaces will be left; all non-applicable items will be marked "N/A". Pertinent forms include:

- Daily Field Report;
- Field Change Request;
- Various Field Instrument Calibration Logs;
- Investigation-Derived Waste Log;
- Water Level Measurement Log;
- Copies of COC Records;
- Drum/Content Identification Form; and
- Daily Decontamination Water Disposal Log, if applicable.

7.4 FINAL EVIDENCE FILE DOCUMENTATION

Records will be kept by the Field Team Leader to document the quality assurance/quality control activities and to provide support for possible evidential proceedings. The following outline of project file requirements applies:

- Communications
  - -- Internal
  - -- External
- Quality Assurance/Quality Control
  - -- Procedures
  - -- Chain-of-Custody
  - -- Audit Reports
  - -- Laboratory Quality Assurance Reports
  - -- Deviation Notification Forms
  - -- Nonconformance/Corrective Action Reports
- Technical Information
  - -- Analytical Data
  - -- Field Data
  - -- Site Logbook
  - -- Field Logbooks

  - -- Field Data Record Forms
  - -- Graphic Resources
  - -- Data Quality Acceptance
  - -- Calculations/Evaluations
  - -- Regulatory Compliance
- Project Management
  - -- Project Schedule
  - -- Budget
  - -- Site Database Information
- Health and Safety
  - -- Plans/Procedures
  - -- Audit Reports
- Documents
  - -- Plans
  - -- Reports
  - -- Relevant Publications

All evidential file documentation will be maintained by the subcontractor under its internal project file system. Upon completion of the project, all records will be delivered to the HAZWRAP Project Manager. Copies of all records will be maintained by the subcontractor for project continuity. The Field Team Leader will ensure that the quality assurance/quality control records are properly stored and retrievable.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 8.0 QUALITY CONTROL FOR FIELD MEASUREMENT DATA

Most data derived for the RI will be developed in the analytical laboratories from the samples collected in the field. However, groundwater sample measurements such as specific conductance, temperature, turbidity, pH, and health and safety monitoring will be performed and recorded in the field. The primary quality assurance objectives of field activities where measurements will be taken are to verify that quality control checks are performed, to verify that measurements were obtained to the degree of accuracy consistent with their intended use, and to provide documentation of adherence to the measurement procedures.

Measurement data will be generated in many field activities including the following:

- Documenting measurement times and weather conditions;
- Locating and determining elevations of sampling locations;
- Using a PID or an OVA to make qualitative organic vapor screening measurements from samples prior to disposal segregation or health and safety monitoring; and
- Measuring pH, conductivity, turbidity, and temperature.

The instruments will be calibrated according to manufacturers' specifications before and after each field use, or as otherwise required. Where necessary, instruments will be calibrated each day during field use.

8.1 SURVEYING

Surveying of all well and soil boring locations at the Base will be conducted to provide a common frame of reference for RI activities. All proposed sample locations will be flagged and surveyed prior to the beginning of the sampling effort. Surveying will be performed by a surveyor registered in the State of Oregon. All samples collection locations, including soil, sediment, surface water, and groundwater, will be surveyed for X, Y and Z coordinates. Surveying will be completed to an accuracy of ± 0.1 foot horizontally and ± 0.01 foot vertically.

All bench marks used will be traceable to a United States Geological Survey (USGS) survey marker.

8.2 ORGANIC VAPOR ANALYZER (OVA)

The OVA or flame ionization detector (FID) is calibrated to a methane standard daily following the manufacturer's specified procedures. The instrument's operation and calibration are checked periodically each sampling day using a solvent-based felt-tip pen, or flammable organic, noting needle deflection (Table 8.1).

8.3 SPECIFIC CONDUCTANCE METER

Calibration is performed at the start of each sampling day using a standard solution of potassium chloride. Adjustment knobs on the meter will be used to set the meter to read the value of the standard. The meter must read within 10% of the standard to be considered in control and should read within 5% (7% is considered a warning level). If the calibration indicates the meter is out of control, a backup unit should be employed; if one is not available, the data will be flagged to note the percent difference between the meter and the standard calibration solution. Readings from conductivity meters lacking calibration adjustments are normally stable; thus, calibration checks are usually limited to checks at the beginning and the end of the sampling day.

8.4 pH METER

Calibration is performed at the start of each sampling day using National Bureau of Standards traceable buffer solutions which bracket the pH range expected in the samples. Calibration knobs are used to set the meter to read the value of the standard. The meter is then checked during the sampling period, using at least one standard, at a frequency which results in little or no calibration adjustment. If the reading varies more than one-tenth of a unit between calibration checks, the frequency of the checks must be increased.

8.5 TEMPERATURE METER

Temperature is measured either using a thermistor built into the specific conductance meter, or by a separate thermometer unit. In all cases, the readings will be checked at least once per field trip using a analytical grade laboratory thermometer (preferably National Bureau of Standards traceable) thermometer. The frequency of calibration, however, is a minimum; should the unit experience erratic or out-of-tolerance readings, additional checks will be performed. Technicians should be especially mindful of subjecting the unit to harsh conditions (e.g., shock, extreme cold, etc.).

8.6 TURBIDITY METER

Calibration is performed at the start of each days sampling event and confirmed before the start of each new well. Calibration is achieved by immersing the probe of the turbidity meter into a clean beaker three quarters full of deionized water and adjusting the turbidity meter readout to a zero reading. Should a calibration check fail to indicate a zero reading, the turbidity probe must be deconned again and a fresh deionized water will be used. If this second check still indicates an above zero reading, the meter may be adjusted to a zero readout.

8.7 DISSOLVED OXYGEN

Dissolved oxygen (DO) content of groundwater samples will be measured in the field using a commercially available test kit. Hach brand test kit 46700-03 or an equivalent colorimetric test kit will be employed with AccuVac or equivalent sampling methods. The analysis will be capable of reporting DO in the range of 0-10 mg/L with reporting increments of 0.1 mg/L. Oxygen (O_2) content of soil gas will be measured using portable industrial hygiene-type equipment (Bacharach LEL-02-PPM or equivalent). The O_2 content of soil gas will be reported in percent O_2 by volume. The reporting range of the instrument is 0-25% O_2 with 0.1% reporting accuracy. Manufacturer recommended reagent handling and storage instructions will be followed. All reagents will be purchased with documented standard accuracy.

8.8 CARBON DIOXIDE

Carbon dioxide, CO_2, concentration of groundwater samples will measured in the field using Hach brand test kit 20341-00 or an equivalent digital titration method . The reporting range is 10-1000 mg/L of CO_2. Oxygen content of soil gas will be measured using portable equipment with a infrared detector. A Riken RI-411 CO_2 Analyzer or equivalent equipment will be used. Measurements of 0-4975 PPM CO_2 may be reported in 25 PPM will increments. Manufacturer recommended reagent handling and storage instructions will be followed. All reagents will be purchased with documented standard accuracy.

8.9 NITRATE, NITRITE, AMMONIA, AND PHOSPHORUS (TOTAL AND REACTIVE)

Due to the variety of parameters (nitrate, nitrite, ammonia, and phosphorus) and the equipment and reagents required to analyze these parameters, field measurement quality data will be generated at the fixed-base laboratory for up to four soil and four groundwater samples at each site. Samples will be collected and shipped to the fixed-base laboratory for field measurement quality analysis and results only reported for the above parameters. Method detection limits, sample volumes, holding times and preservation requirements are listed in Table 8.2. No field QC samples or extra volumes of environmental samples for laboratory QC will be collected. Sample quantities listed in Table 8.2 are approximate.

Table 8.1
Field Measurement Equipment Calibration Frequency
142nd Fighter Group, Oregon Air National Guard
Portland International Airport, Portland, Oregon

Instrument	Calibration Standard	Frequency	Tolerance
OVA	10 PPM methane	Daily	NA
Specific Conductance Meter	KCl	Daily	± 10%
pH Meter	NBS traceable standards	Minimum of twice daily	0.1 pH units
Temperature Meter	NBS traceable thermometer	Prior to first measurement after mobilization of field effort	1° C
Turbidity Meter	Standard turbidity suspension	Prior to first measurement and after every well	±3 NTU

OVA = Organic vapor analysis.
PPM = parts per million.
° C = degrees Celsius.
KCl = Potassium chloride.
NA = Not Applicable.
NBS = National Bureau of Standards.

Table 8.2
Field Measurement Data for Fixed-base Laboratory Analysis
Detection Limits, Volumes, Containers, Preservation, and Holding Summary

	Soil	36		1.0 mg/kg		500-mL P	Cool to 4°C
Phosphorus	Water	43	MCAWW* 365.4**	0.10 mg/L	28 days	250-mL P	Cool to 4°C, H_2SO_4 to pH<2
	Soil	36		25 mg/kg		250-mL P	

*MCAWW=Methods for Chemical Analysis of Water and Wastes
**Field parameters will be based on USEPA approved methods listed but will not adhere to definitive level data analysis requirements. Soil extraction will be required for all soil/sediment samples.
extn=time to extraction
°C = degrees Celsius
anal=time to analysis
g = gram
mL = milliliter
d = day
h = hour
P = Plastic
NA = Not applicable

SECTION 9.0 DATA REDUCTION, SUBSTANTIATION, AND REPORTING

Data reduction is the process of converting raw data to a useable format. Data substantiation is a mixture of verification and evaluation procedures which assess the useability of data at an intended data quality level or DQO.

9.1 FIELD AND TECHNICAL DATA

The field and technical (non-laboratory) data that will be collected during the RI can generally be characterized as either objective or subjective data. Objective data include all direct measurements, such as field screening/analytical parameters and water level measurements. Subjective data include activity descriptions and observations.

9.1.1 Field and Technical Data Reduction

All field data will be recorded by field personnel in bound field notebooks and on standard forms. For example, during RI field activities, the field team member supervising the drilling and/or sampling activities will keep a chronological log of activities, a vertical descriptive log of lithologies encountered, other pertinent information (staining, odors, field screening, working conditions, water levels, etc.), and a labor and materials accounting in his/her bound notebook. The Field Team Leader may choose to appoint a team member to photocopy all field logs (including notebook pages and standard forms) generated in a given field day. Copies will be given to the Field Team Leader who will maintain all field log files. At the direction of the Field Team Leader, copies of all field logs, notebook pages, and standard forms will be returned to the field office for entry into project files.

After checking the validity of data in the field notes and on standard forms, the Field Team Leader will be responsible for entering pertinent data into data files. Where appropriate, the data files will be set up for direct input into the project data base. Subjective data will be filed as hard copies for later review by the Project Manager and Field Team Leader for incorporation into technical reports as appropriate.

9.1.2 Field and Technical Data Substantiation

Substantiation of field activities is primarily a verification that proper procedures were followed while taking measurements related to samples, locations and survey information, etc.

Typical measurements include:

- Soil sample location measurement;
- Water level measurements;
- OVA/PID readings; and
- pH, temperature, turbidity, and specific conductance.

Field measurements are considered valid provided that:

- Calibration records for field measurement equipment are properly maintained;

- Training records exist which document that field personnel are familiar with standard procedures for taking measurements; and

- Verification that calculations and observations are accurately recorded and transcribed.

Substantiation of objective field and technical data will be performed at two different levels. On the first level, data will be substantiated at the time of collection by following standard procedures and quality control checks. At the second level, data will be substantiated by the Field Team Leader, who will review the data to ensure that the correct codes and units have been included. After data reduction into tables or the project data base, the Field Team Leader will review data sets for anomalous values. Any inconsistencies or anomalies discovered will be resolved immediately, if possible, by seeking clarification from field personnel responsible for collecting the data. Subjective field and technical data will be substantiated by the Field Team Leader, who will review field reports for reasonableness and completeness. In addition, random checks of sampling and field conditions will be made by the Field Team Leader and Quality Assurance Manager who will check recorded data at that time to confirm the recorded observations. Whenever possible, peer review will also be incorporated into the data substantiation process, particularly for subjective data, to maximize the consistency among field personnel. For example, during RI field activities, the Project Manager will schedule periodic

reviews of archived lithologic samples to ensure the proper lithologic descriptions and codes have been consistently applied by field personnel.

9.2 LABORATORY DATA VERIFICATION

All data collected during the remedial investigation will be internally verified by the Analytical Services Manager by reviewing the data packages for method QC compliance including calibration frequency and acceptance criteria, method blank analysis, and matrix spike analysis. The Analytical Services Manager will also review sample analyses within holding time and turn-around time requirements, and complete sample analysis against the COC.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 10.0 ANALYTICAL DATA REPORTING AND VALIDATION

10.1 FIELD LABORATORY DATA REPORTING AND VALIDATION

10.1.1 Hard Copy Data

Field laboratory analytical results will be reported as soon as results are available, typically within 48 hours of sample receipt for soils and 24 hours from sample receipt for water samples. The complete data package including laboratory QC results will be due within 30 days of sample receipt. At a minimum, the following will be reported for the quick turn results:

- Laboratory name and address;
- Analyst;
- Sample ID as provided by the field team;
- Sample ID assigned by the laboratory;
- Data and time of sample receipt;
- Sample X, Y and Z coordinates;
- Date and time of analysis;
- Type of sample (water/soil);
- Type of analysis/method number;
- Concentration of compound detected;
- Detection limit of compounds not detected;
- Sample weight/volume;
- percent moisture (dry weight calculations for soils);
- Dilution factor; and
- Comments or remarks.

Thirty days after sample receipt, the mobile laboratory will be required to submit a data package containing all laboratory deliverables listed in Table 10.1 to the Subcontractor Analytical Services Manager for verification. This data package must contain all CLP forms listed in Table 10.1. The data will be verified by the Subcontractor chemist.

The field laboratory will be required to maintain all sample analysis information data including but not limited to standards and instrument log books, all CLP-type summary forms and all raw data for the entire field effort. The field laboratory will archive all information and data

Table 10.1
Field Laboratory Data Deliverables
142nd Fighter Group, OANG
Portland International Airport, Portland, Oregon

Method Requirements	Deliverables
GC/MS Field Methods	
Holding time information and methods requested.	Signed chain-of-custody forms
Discussion of laboratory problems	Case narratives
Environmental and QC sample Results[1]	CLP Form 1 or equivalent
Surrogate recoveries. Surrogates to be used in VOCs and SVOCs	CLP Form 2 or equivalent
Matrix spike/spike duplicate. One spike and spike duplicate per 20 samples of a similar matrix for soil VOCs and all SVOCs	CLP Form 3 or equivalent
Method blank data	CLP Form 4 or equivalent
GC/MS tuning for volatiles/semivolatiles	CLP Form 5 or equivalent
GS/MS initial calibration data for volatiles/semivolatiles	CLP Form 6 or equivalent
GS/MS continuing calibration data	CLP Form 7 or equivalent
GC/MS internal standard area data	CLP Form 8 or equivalent

OANG - Oregon Air National Guard.

[1]Should included Form I results for matrix spike/ matrix spike duplicate, method blanks, instrument blanks, and trip blanks.

QC = Quality Control.

PCBs = Polychlorinated Biphenyls.

GC/MS = Gas Chromatograph/Mass Spectrometers.

CLP = Contract Laboratory Package.

for a period of five years after completion of the field effort and will submit all deliverables upon request of the ANG, HAZWRAP, or the OANG.

10.1.2 Field Laboratory Electronic Data

Analytical results are required to be delivered electronically concurrently with the 24- to 48-hour field results in a database format. Ten percent of all analytical data directly transferred from the instrument to the database format must be verified by a laboratory technician to ensure transfer integrity. Any hand entries, required such as sample identification or percent moisture, must be verified by a laboratory technician by comparing against hard copy data. The laboratory will be responsible for including entries for the following fields:

- Client Sample ID;
- Laboratory Sample ID;
- Date and Time of Analysis;
- Type of sample;
- Type of analysis;
- Concentration of compounds detected;
- Detection limit or reporting limit of compounds not detected;
- Sample weight/volume;
- percent moisture (dry weight calculations for soils);
- Dilution Factor;
- Laboratory flags; and
- Comments or Remarks.

The subcontractor Data Evaluation Manager will be responsible for verifying the laboratory electronic data deliverable against the hard copy sample results and the COC for completeness and correctness. After verifying the electronic data deliverable (EDD), the Data Evaluation Manager will be responsible for loading the data into the database to generate 2-dimensional contour maps using MicroSoft™ Windows Paintbrush software in the Real-Time Interpretation System (R-TIS) program. The Data Evaluation Manager will submit the updated database to the Field Team Leader or a qualified designee for interpretation of results. The Data Evaluation Manager may perform data queries under the direction of the Project Manager or Field Team Leader (Figure 10.1).

10.1.3 Field Laboratory Data Validation

All data packages generated by the field laboratory will be examined by an independent validator. Data validation guidelines are located in Attachment A. The data packages will be forwarded to the validators after initial verification by the Analytical Services Manager.

Upon completion of the verification, the Analytical Services Manager will forward the data package to the validators. Data validation packages will be required to be completed and returned to the Analytical Services Manager within 30 days from date of receipt. Validated packages will be reviewed and validation flags input into the database. Figure 10.1 shows the flow of data through the data collection and validation process.

10.2 FIXED-BASE LABORATORY DATA REPORTING AND VALIDATION

10.2.1 Hard Copy Data

Sample results must be submitted to the Field Team Leader within seven days of sample receipt by the fixed-base laboratory. The results must contain the following information:

- Laboratory name and address;
- Analyst;
- Sample ID as provided by the field team;
- Sample ID assigned by the laboratory;
- Date and time of sample receipt;
- Sample X, Y and Z coordinates;
- Date and time of analysis;
- Type of sample (water/soil);
- Type of analysis/method number;
- Concentration of compound detected;
- Detection limit of compounds not detected;

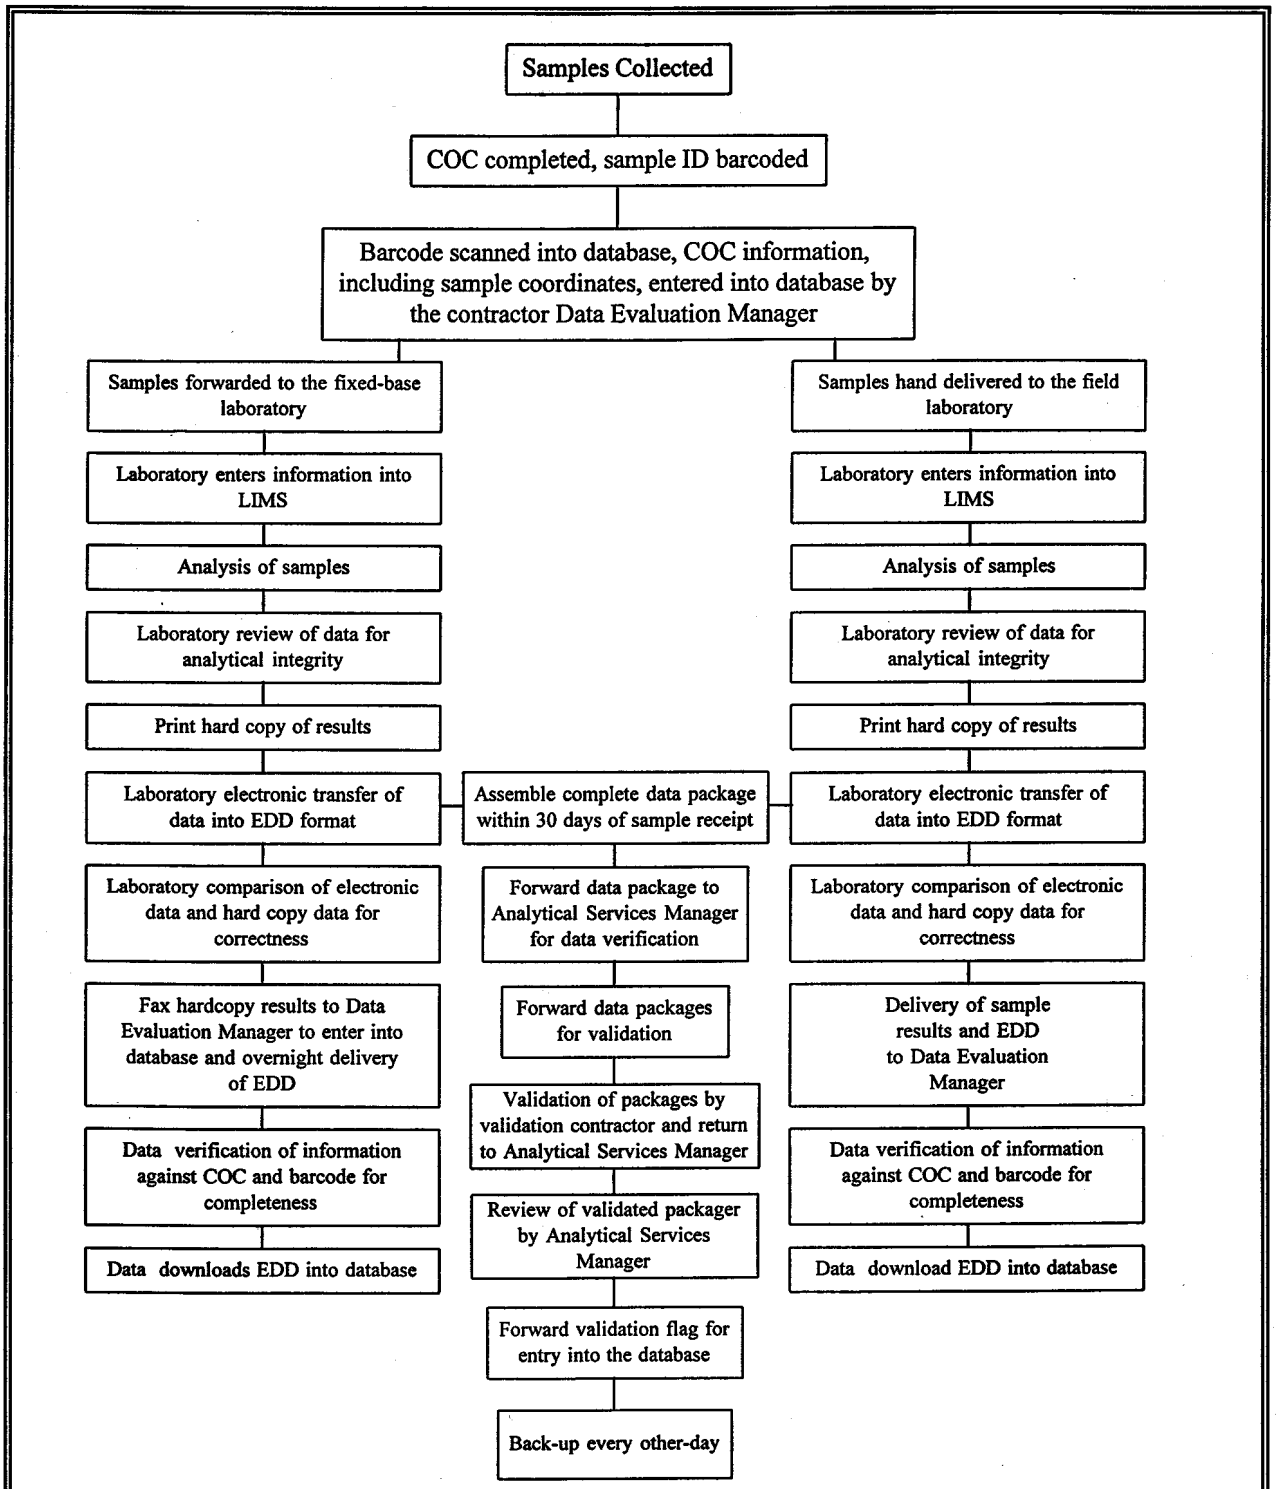

Figure 10.1 — **Data Collection and Validation Process**
142nd Fighter Group, Oregon Air National Guard
Portland International Airport, Portland, Oregon

OPTECH Operational Technologies CORPORATION

- Sample weight/volume;
- percent moisture (dry weight calculations for soils);
- Dilution factor; and
- Comments or remarks.

Complete sample data packages from the fixed-base laboratory are required to be submitted to the Analytical Services Manager within 30 days of sample receipt. Data packages will meet HAZWRAP Level C deliverables requirements. Data packages must contain the appropriate CLP-type forms for each analysis (Table 10.2).

10.2.2 Fixed-Base Laboratory Electronic Deliverables

Analytical results will be required to be delivered electronically concurrently with complete Level C data package in a Microsoft™ Access or similar database format. Ten percent of all analytical data directly transferred from the instrument data station to the database format must be verified by a laboratory technician for transfer integrity. Any hand entries required, such as sample identification, percent moisture or wet chemistry data, must be verified by a laboratory technician by comparison against hard copy data. The laboratory will be responsible for including entries for the following fields:

- Client Sample ID;
- Laboratory Sample ID;
- Date and Time of Analysis;
- Type of sample;
- Type of analysis;
- Concentration of compounds detected;
- Detection limit or reporting limit of compounds not detected;
- Sample weight/volume;
- percent moisture (dry weight calculations for soils);
- Dilution Factor;
- Laboratory flags; and
- Comments or Remarks.

Method Requirements	Deliverables
Requirements for all methods:	
Holding time information and methods requested	Signed chain-of-custody forms
Discussion of laboratory problems	Case narratives
LCS with results on control charts. Run with each batch of samples processed.	Control charts.
Organics:	
Sample results	CLP Form 1 or equivalent.
Surrogate recoveries. Surrogates to be used in volatiles, and semivolatiles. TPH will not require a surrogate spike.	CLP Form 2 or equivalent.
Matrix spikes/spike duplicate. One spike and spike duplicate per 20 samples of similar matrix for VOCs, SVOCs, and TPH.	CLP Form 3 or equivalent.
Method blank data.	CLP Form 4 or equivalent.
GC/MS tuning for volatiles/semivolatiles	CLP Form 5 or equivalent.
GC/MS/GC initial calibration data for volatiles, semivolatiles, and TPH	CLP Form 6 or equivalent.
TPH identification summary form	CLP Form 10 or equivalent.
GC/MS&GC continuing calibration data	CLP Form 7 or equivalent.
GC/MS internal standard area data and analytical sequence	CLP Form 8 or equivalent.
Metals:	
Sample results	CLP Form 1 or equivalent.
Initial and continuing calibration	CLP Form 2 or equivalent.
Blank results	CLP Form 3 or equivalent.
ICP interference check sample	CLP Form 4 or equivalent.
Spike sample recovery (one per 20 samples of similar matrix)	CLP Form 5A or equivalent.
Postdigestion spike sample recovery for ICP metals. Only done if predigest spike recovery exceeds CLP limits.	CLP Form 5B or equivalent.
Duplicates (one per 20 samples will be split and digested as separate samples)	CLP Form 6 or equivalent.
LCS	CLP Form 7 or equivalent.
Standard addition. The decision process outlined in CLP Page E-3 will be used to determine when standard additions are required	CLP Form 8 or equivalent.
Instrument detection limit	CLP Form 10 or equivalent.

Table 10.2 (Concluded)
Fixed-Base Laboratory Data Package Deliverables
142nd Fighter Group, OANG
Portland International Airport
Portland, Oregon

Method Requirements	Deliverables
Metals, Continued.	
ICP serial dilution	CLP Form 9 or equivalent.
ICP interelement correction factors	CLP Form 11 or equivalent.
ICP linear range	CLP Form 12 or equivalent.
Sample preparation	CLP Form 13 or equivalent.
Analytical run log including post digestion analytical spike recovery	CLP Form 14 or equivalent.

*Must be reported in the data package with which the analysis is batched. May be referenced in case narrative for associated analyses that are not included in the reporting group.

**Limited calibration data must be presented in the first data package associated with the ICAL. Remaining data packages may reference the ICAL in the case narrative not supply additional summary forms.

CLP = Contract Laboratory Package.

LCS = Laboratory Control Standard.

GC/MS = Gas Chromatography/Mass Spectrography.

ICP = Inductively Coupled Plasma.

ICAL = Initial Calibration.

The subcontractor data evaluation manager will be responsible for verifying the laboratory electronic data deliverable against the hard copy sample results and the COC for completeness and correctness. After verifying the EDD the data evaluation manager will be responsible for loading the data into the database to generate 2-dimensional contour maps using Microsoft™ Windows Paintbrush software in the Real-Time Interpretation System (R-TIS) program. The data evaluation manager will submit the updated database to the Field Team Leader or a qualified designee for interpretation of results. The data evaluation manager may perform data queries under the direction of the Field Team Leader.

10.2.3 Fixed-Base Laboratory Data Validation

All level C data packages will be validated by an independent validator. Validation of the methods will follow the general logic of the functional guidelines but specific review will be modified to meet method requirements. Validation guidelines are presented in Attachment A.

The data packages will be forwarded to the validators after initial verification by the Analytical Services Manager. The verification process is explained in section 9.2 of the QAPP. Upon completion of verification the Analytical Services Manager will forward the data package to the validators. Data validation packages will be required to be completed and returned to the Analytical Services Manager 30 days from date of receipt. Validated packages will be reviewed and validation flags input into the database. Figure 10.1 shows the flow of data through the data collection and validation process.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 11.0 PERFORMANCE AND SYSTEM AUDITS

Audits may consist of two types, system audits and performance audits. The purpose of a system audit is to determine whether appropriate project systems are in place. Performance audits are used to indicate whether those systems are functioning properly. Audits will be conducted by Subcontractor's project Quality Assurance Manager as tasked by the Project Manager to verify the existence of an effective quality control system. Additionally, the audit will evaluate the level of compliance of that system in terms of adherence to quality control measures, standards, records, and project documentation and control.

11.1 PROJECT SYSTEM AUDITS

The Quality Assurance Manager will periodically, on an unannounced basis, call for a system audit. The Project Manager will respond by submitting the QAPP. The auditor will then determine whether the QAPP is in place and whether the reviews called for by the QAPP have been performed. Results of project audits will be reported to the Project Manager.

11.2 TECHNICAL PERFORMANCE AUDITS

Technical performance audits will be conducted by the project QA manager on an ongoing basis during the project, as field data are generated, reduced, and analyzed. All numerical analyses, including manual calculations, mapping, and computer support activities, will be documented and will be subject to performance audits in the form of quality control procedural reviews, mathematical reanalysis, and peer review. Technical peer review is the responsibility of the Project Manager. All records of numerical analyses will be legible, reproduction quality, and complete enough to permit logical reconstruction by a qualified objective reviewer.

11.3 FIELD AUDITS

A field performance audit will be conducted by the Data Management and Analytical Data Evaluation Manager at the beginning of the field effort. The Data Management and Analytical Data Evaluation Manager will closely monitor the mobile laboratory's performance continually through out the course of the field work. The purpose of the field audit is to ensure that proper methods and protocols detailed in this QAPP are consistently practiced in the field. Audits will be performed using tailored checklists prepared by the Quality

Assurance Manager. The requirements and audit questions to be developed will be as specific as possible and will focus on significant investigative techniques. Checklists are encouraged to be completed to the maximum extent possible to give a complete picture of field techniques using a structured approach.

Field operation records will be reviewed to verify that field-related activities have been performed in accordance with appropriate project procedures. Items reviewed will include, but are not limited to, field equipment calibration records, daily field logs, and chain-of-custody documentation.

Upon audit completion, an audit report containing observations and findings and recommended corrective actions will be submitted to the Project Manager.

11.4 LABORATORY AUDITS

The laboratory QA Manager has responsibility for monitoring the internal quality assurance program. The subcontractor will verify that standardized quality assurance programs are in effect to provide objective oversight of laboratory procedures. Additionally, copies of internal quality assurance reports will be requested to ensure standards of quality performance are in effect. The field laboratory will be audited at the beginning of the field effort and monitored closely throughout the project.

SECTION 12.0 PREVENTATIVE MAINTENANCE

Preventive maintenance is an organized program of actions taken to maintain proper instrument and equipment performance and to prevent instruments and equipment from failing during use. An adequate preventive maintenance program increases reliability of a measurement system, and minimizes downtime of field and laboratory instruments.

12.1 FIELD EQUIPMENT

Field equipment will be properly calibrated, charged, and in good working condition before the beginning of each working day. Manufacturers' specifications define the required equipment checks for each type of field equipment used. Non-operational field equipment will be removed from service and a replacement will be obtained within 24 hours. Significant repairs to field equipment will not be performed in the field.

All field instruments will be properly protected against inclement weather during the field investigation. Each instrument is specially designed to maintain its operating integrity during variable temperature ranges that are representative of ranges that will be encountered during working conditions. At the end of each working day, all field equipment will be taken out of the field and placed in a cool, dry room for overnight storage.

All sub-tier contractor equipment (e.g., drilling rig) will arrive at the site in proper working condition. All lubricating and hydraulic motor oils will be checked by the sub-tier contractor before the start of each work day to ensure all fluid reservoirs are full and there are no leaks. Before the start of each work day, the Field Team Leader will also inspect all equipment for fluid leaks. If a leak is detected, the equipment will be removed from service for repair or replacement.

12.2 LABORATORY EQUIPMENT

The ability to generate valid analytical data requires that all analytical instrumentation be properly maintained. Only approved laboratories that have undergone extensive audits by HAZWRAP will be considered for fixed-base laboratory analysis. The mobile laboratory will be required to submit a Laboratory Quality Assurance Plan in accordance with DOE/HWP/65 requirements addressing laboratory equipment maintenance.

THIS PAGE INTENTIONALLY LEFT BLANK

SECTION 13.0 CORRECTIVE ACTION PROTOCOLS

The Quality Assurance Manager will prepare a formal report of all audit proceedings. The programmatic impact of a negative finding, such as the lack of or a failure to use an appropriate procedure, will be determined by the Quality Assurance Manager and reported to the project management staff. A corrective action plan and implementation schedule will be required, and the Project Manager will be responsible for ensuring that immediate action to correct the nonconformance has been initiated. The Project Manager will be responsible for ensuring the successful implementation of the corrective action plan and ensuring that no additional work that is dependent on the nonconforming action is performed until the nonconformance is corrected. Corrective action may include reanalyzing samples if holding times permit, resampling, and evaluating and amending sampling and analytical processes.

The Project Manager will be responsible for ensuring that the corrective action adequately addresses the nonconformance. The Quality Assurance Manager will ensure that corrective actions for nonconformance are implemented by:

- Evaluating all reported nonconformances;
- Controlling additional work on nonconforming items;
- Maintaining the log of nonconformances; and
- Ensuring nonconformance and corrective action reports are included in the site documentation files.

Following implementation of satisfactory corrective action, the Quality Assurance Manager will conduct follow-up activities sufficient to verify implementation of the corrective action. Such confirmation will be documented, along with any other recommendations, in a formal close-out of the audit. The closeout report will be distributed to all appropriate project management personnel.

13.1 FIELD CORRECTIVE ACTION

The initial responsibility for monitoring the quality of field measurements and observations lies with field personnel. The Field Team Leader and the Project Manager are responsible for verifying that all quality control procedures are being followed. This requires that the Field Team Leader assess the correctness of field methods and the ability to meet quality assurance objectives. If a problem occurs that might jeopardize the integrity of the project or cause some

specific quality assurance objective not to be met, it is the responsibility of all field project staff to report all suspected nonconformances by initiating a nonconformance report and submitting it to the Project Manager.

The Project Manager will submit a copy of the nonconformance report to the Quality Assurance Manager for formal investigation. An appropriate corrective action will then be decided upon and implemented. The Project Manager will document the problem, the corrective action, and the results, using the form shown in Figure 13.1. Copies of the documentation form will be provided the Project Manager and the Quality Assurance Manager.

13.2 LABORATORY CORRECTIVE ACTION

The initial responsibility to monitor the quality of an analytical system lies with the analyst. In this regard, the analyst will verify that all quality control procedures are followed and that the results of analyses of quality control samples are within acceptance criteria. This requires that the analyst assess the correctness of all of the following items, where appropriate:

- Sample preparation procedures;
- Initial calibration;
- Calibration verification;
- Method blank result; and
- Laboratory control standards.

If this assessment reveals that any of the quality control acceptance criteria have not been met, as defined by the lab's most recent QAPP or USEPA SW-846 (USEPA, 1986) standards, the analyst must immediately assess the analytical system to correct the problem. The analyst notifies his/her supervisor, section leader, or quality assurance coordinator of the problem and, if possible, identifies the potential cause(s) and makes appropriate corrective action recommendations.

FIGURE 13.1

FORM\CORRACTN

CORRECTIVE ACTION FORM (REDUCED)
142nd FG. Portland International Airport
Portland, Oregon

OPTECH
OPERATIONAL TECHNOLOGIES CORPORATION

October 1995

The identification of the corrective action obviously depends on the nature of the problem. For example, if a continuing calibration verification is determined to be out of process control, the corrective action may require recalibration of the analytical system and reanalysis of all samples since the last acceptable continuing calibration standard.

Sample-related quality control samples (e.g., matrix spikes and duplicates) provide an indication of matrix effects on analyses and do not require reanalysis if method-related quality control samples (e.g., method blanks, method spikes, and method spike duplicates) indicate acceptable performance.

When the appropriate corrective action measures have been defined and the analytical system is determined to be in control, the analyst documents the problem, the corrective action, and the data, thereby clearly demonstrating that the analytical system is in control. Copies of the documentation are provided to appropriate management staff members and the Quality Assurance Manager, for eventual addition to the project files.

SECTION 14.0 QUALITY ASSURANCE REPORTS TO MANAGEMENT

The Project Manager will rely on written reports and memoranda documenting data assessment activities, quality audits, nonconformances, corrective actions, and quality notices. A copy of all significant quality assurance reports will be forwarded to the appropriate management levels for review and oversight.

THIS PAGE INTENTIONALLY LEFT BLANK

DATA VALIDATION CRITERIA FOR METALS

Validation for metals and cyanide will essentially follow the CLP functional guidelines. Refer to Table 10.2 of QAPjP for laboratory data deliverables.

1.0 Technical Holding Time

1.1 Review Items

COC forms, case narrative, sample receipt checklist, sample preparation log, and analytical run log.

1.2 Criteria

Holding time requirements listed below apply to preserved samples and are from the date of sample collection to date of analysis.

METALS (except mercury):	180 d
MERCURY:	28 d

1.3 Evaluation

Compare the sampling date from the COC form with the dates of analysis found on the analytical run log to establish sample holding times. Examine the sample receipt checklist and COC form to verify proper sample preservation.

1.4 Action

- o If criteria for holding times are exceeded or samples were not properly preserved, qualify all results greater than IDL (positive results) as estimated (J), and results less than IDL (nondetects) as estimated (UJ).

- If holding times are grossly exceeded (i.e., by a factor of two or more), the expected bias would be low and the validator may determine that results less than IDL (nondetects) should be qualified as unusable (R).

2.0 Instrument Calibration and Calibration Verification

2.1 Review Items

Form 2 or equivalent, sample preparation log, and analytical run log.

2.2 Criteria

o Initial Calibration: Instruments must be calibrated daily and each time they are set up.

- For ICP analysis, a blank and at least one standard must be used in establishing the analytical curve.

- For AA analysis, a blank and at least three standards, one of which must be at the PDL specified by the CLP method (or laboratory reporting limit for non-CLP methods) must be used in establishing the calibration curve.

- For mercury analysis, a blank and at least four standards must be used in establishing the analytical curve.

o Initial and Continuing Calibration Verification (CCV):

- Analytical results must fall within the control limits of 90-110 %R of the true value for all analytes except mercury.

- Analytical results for mercury must fall within the control limits of 80-120 %R.

2.3 Evaluation

By examining review items listed above, verify specified criteria for instrument calibration and calibration verifications were met for the analytical method performed.

2.4 Action

o If the minimum number of standards is not used for initial calibration, the reviewer should use professional judgment to qualify data. However, if the instrument is not calibrated daily and each time it is set up, qualify data (detects and nondetects) as unusable (R).

- o If the ICV or CCV %R falls outside acceptance windows, the following action is to be taken:

  - If %R is between 75-89 percent or 111-125 percent (70-84 percent or 116-130 percent for cyanide, 65-79 percent or 121-135 percent for mercury), qualify results greater than IDL as estimated (J).

  - If %R is within the range of 111-125 percent (116-130 percent for cyanide, 121-135 percent for mercury), results less than IDL are acceptable.

  - If %R is 75-89 percent (70-84 percent for cyanide, 65-79 percent for mercury), qualify results less than IDL as estimated (UJ).

  - If %R is > 125 percent (> 130 percent for cyanide, > 135 percent for mercury), qualify results greater than or equal to IDL as unusable (R); results less than IDL are acceptable.

  - If %R is < 75 percent (< 70 percent for cyanide, < 65 percent for mercury), qualify all results (detects and nondetects) as unusable (R).

3.0 Laboratory Blanks

3.1 Review Items

Form 3, sample preparation log, and analytical run log.

3.2 Criteria

- o No contaminants should be present in the blanks.

- o At least 1 preparation blank must be processed and analyzed with each batch of samples (not to exceed 20 samples).

- o A calibration blank must be analyzed at each wavelength used for analysis immediately after every ICV and CCV, at a frequency of 10 percent or every 2 h during the run, whichever is more frequent.

- o The criteria for evaluation of blanks applies to any laboratory blank [preparation blank, initial calibration blank (ICB), continuing calibration blank (CCB)] associated with samples. Qualification of data should be based upon a comparison with the associated blank having the highest concentration of a contaminant.

3.3 Evaluation

Review blank results reported on Form 3. Verify a preparation blank has been reported per matrix for each digestion batch, and an instrument blank (ICB and CCB) has been analyzed immediately after every ICV and CCV, and after the last sample.

3.4 Action

- o If a blank result has an absolute value less than IDL, no qualification of data is necessary.

- o If the reported blank result is greater than or equal to IDL, qualify all sample results greater than or equal to IDL but < 5X the amount in any blank, as undetected (U).

- o If the blank result is negative, and the absolute value is greater than IDL, all associated samples must be examined. Sample results reported as positive but < 5X the absolute value of the blank will be qualified as estimated (J), and sample results reported as undetected will be qualified as estimated (UJ).

- o Sample results > 5X the blank concentration require no qualification.

NOTE: Laboratory blank analyses may not involve the same weights, volumes, or dilution factors as associated samples, and reported results for soil samples will not be in the same units as calibration blank data. In addition, the reviewer may need to consider the percentage of moisture for soils reported on a dry weight basis. These factors must be taken into consideration when qualifying data based on laboratory blank results.

SAMPLE RESULTS MUST NOT BE CORRECTED BY SUBTRACTING ANY BLANK VALUE.

Table 1
Example of Analyte Concentration Equivalents (Mg/L) Arising From Interferents at the 100 mg/L Level

Analyte	Wavelength (nm)	Interferent									
		Al	Ca	Cr	Cu	Fe	Mg	Mn	Ni	Ti	V

4.0 Equipment Rinseates and ASTM Type II Source Water Check Samples

4.1 Review Items

Results for equipment rinseates and ASTM Type II source water check samples associated with the collection of environmental samples and decontamination of sampling equipment.

4.2 Criteria

Ideally, no target analytes should be present in equipment rinseates and ASTM Type II source water check samples.

4.3 Evaluation

Review associated equipment rinseates and ASTM Type II source water results to determine if contamination has resulted due to sample collection and equipment decontamination procedures.

4.4 Action

Use professional judgment when qualifying sample results based on equipment rinseates and ASTM Type II source water results. All equipment rinseate and ASTM Type II source water check samples collected during the sampling event or field effort may need to be reviewed to determine if trends in contamination are occurring. For example, if one analyte is detected in 80 percent of environmental samples, but only appears in 5 percent of the associated equipment rinseate samples, this is probably indicative of environmental contamination and sample results should not be qualified.

5.0 Inductively Coupled Plasma Interference Check Sample

5.1 Review Items

Form 4. Refer to Table 1 for recommended interferant and analyte elemental concentrations used for ICS solutions.

5.2 Criteria

- An ICS must be analyzed at the beginning and end of each sample run, or twice every 8 h, whichever is more frequent.

- Results for ICS solution AB analysis must fall within the control limits of ± 20 percent of the true value.

5.3 Evaluation

Verify that ICS-A and ICS-AB solutions were analyzed at the required frequency and that concentrations reported on Form 4 are within required control limits.

5.4 Action

- In general, sample data are acceptable if the concentrations of aluminum, calcium, iron, and magnesium in the sample are found to be less than or equal to their respective concentrations in the ICS. If these elements are present at concentrations greater than levels in the ICS, or other elements are present in the sample at > 10 mg/L, the possibility of other interference effects should be investigated by using Table 2 on page D-26 of ILMO3.0 (see next page). The concentration produced by an interfering element should be estimated, and if the estimate is > 2X PDL and also > 10 percent of the reported concentration of the affected element, qualify affected results as estimated (J).

- For samples with concentrations of aluminum, calcium, iron, and magnesium comparable to or greater than their respective levels in the ICS:

  - If ICS recovery for an element is > 120 percent and sample results are less than IDL, no qualification is necessary. Qualify sample results greater than IDL as estimated (J).

  - If ICS recovery for an element is 50-79 percent, qualify sample results greater than IDL as estimated (J), and results less than IDL as estimated (UJ).

- If ICS recovery results for an element are < 50 percent, qualify the affected data (detects and nondetects) as unusable (R).

o If results greater than IDL are reported for elements not present in the ICS solution, the possibility of false positives exists. Associated sample data for the affected elements should be evaluated. For samples with comparable or higher levels of interferents, or with analyte concentrations that approximate the levels found in the ICS (false positive), qualify sample results greater than IDL as estimated (J).

o If negative results having an absolute value greater than IDL are observed for elements not present in ICS solutions, the possibility of false negatives in the samples may exist. For samples with comparable or higher levels of interferents, qualify results for the affected analytes less than IDL as estimated (UJ).

o If ICS check samples were not analyzed at the required frequency, all QC information must be carefully reviewed when evaluating data.

6.0 Laboratory Control Samples

6.1 Review Items

Form 7, sample preparation log, and analytical run log.

6.2 Criteria

o All aqueous LCS results must fall within the control limits of 80-120 %R, except antimony and silver which have no control limits. An aqueous LCS is not required for mercury analysis. For cyanide, a distilled ICV is used as the LCS.

o All solid LCS results must fall within the established control limits specified on Form 7.

6.3 Evaluation

Review Form 7, sample preparation log, and analytical run log to verify LCS %R is within specified control limits.

6.4 Action

- Aqueous LCS
  - If LCS recovery of any analyte (except antimony and silver) falls within the range of 50-79 percent or > 120 percent, qualify results greater than IDL as estimated (J).
  - If sample results are less than IDL and LCS recovery is > 120 percent, data are acceptable and no qualification is required.
  - If sample results are less than IDL and LCS recovery falls within the range of 50-79 percent, qualify data for the affected analyte as estimated (UJ).
  - If LCS recovery results are < 50 percent, qualify associated sample results (detects and nondetects) for the affected analyte as unusable (R).
- Solid LCS
  - If the solid LCS recovery for any analyte falls outside established control limits, qualify all sample results greater than IDL as estimated (J).
  - If LCS results are higher than control limits and sample results are less than IDL, data are acceptable and no qualification is required.
  - If LCS results for an analyte are lower than control limits, qualify all sample results less than IDL as estimated (UJ).

7.0 Laboratory Duplicate Sample Analysis

7.1 Review Items

Form 6, sample preparation log, and analytical run log.

7.2 Criteria

- Samples identified as field QC samples are not to be used for duplicate sample analysis.

- One duplicate sample must be prepared and analyzed from each group of samples with a similar matrix type, or for each SDG.

- A control limit of ± 20 percent for aqueous samples (± 35 percent for soil samples) for RPD is applied to sample results > 5X PDL (or the reporting limit).

- A control limit of plus or minus PDL or reporting limits (± 2X PDL or reporting limit for soil) is applied to sample results < 5X PDL (or the reporting limit), including the case when only one duplicate sample results is < 5X PDL (or the reporting limit).

  NOTE: Some EPA regions may require that control limits of ± 20 percent RPD and plus or minus PDL (or the reporting limit) be applied, regardless of sample matrix type.

7.3 Evaluation

Review Form 6 and verify that RPD values are within control limits. Recalculate one or more RPD values using the following equation:

$$RPD = \frac{|S-D|}{(S+D)/2} \times 100$$

Where:

S = First sample value (original)
D = Second sample value (duplicate)

7.4 Action

- o If duplicate analysis results for a particular analyte are > 5X PDL/reporting limit and RPD is not within 20 percent for aqueous (35 percent for soil) samples, qualify the results for that analyte in all associated samples of the same matrix as estimated (J).

- o If one or both sample results are < 5X PDL/reporting limits, and the duplicate sample result for a particular analyte is not within plus or minus PDL/reporting limit of the original aqueous (± 2X PDL/reporting limit for soil) sample result, associated samples of the same matrix are qualified as estimated (J/UJ).

- o If a field QC sample was used for duplicate analysis, all other QC data must be carefully checked when evaluating the data.

8.0 Field Duplicate Analysis

8.1 Review Items

Validated results for samples identified as field duplicates.

8.2 Criteria

Field duplicate analyses measure both field and laboratory precision and, therefore, may have more variability than laboratory duplicates that measure only laboratory performance. The criteria used to evaluate field duplicates must be specified in the project WP. In the absence of specified criteria, the following guidelines are recommended:

- o For sample results > 5X PDL or the reporting limit, a control limit of ± 40 RPD for water (± 70 RPD for soil) may be used.

- o For sample results < 5X PDL or the reporting limit, a control limit of ± 2X PDL or the reporting limit for waters (± 4X PDL or reporting limit for soils) may be used.

8.3 Evaluation

Compare results for samples identified as field duplicates and calculate the RPD between results.

8.4 Action

Generally, no action is taken on the basis of field duplicate results. Results that fall outside criteria specified in the project WP, or limits recommended above, should be noted during data validation and discussed in the QC summary section of the project final report.

9.0 Matrix Spike Sample Analysis

9.1 Review Items

Form 5A, sample preparation log, and analytical run log.

9.2 Criteria

- Samples identified as field QC samples cannot be used for MS analysis. HAZWRAP requires that MS analysis be performed on a sample from the HAZWRAP project being validated.

- MSs must be analyzed at a frequency of 1 per 20 or less samples of similar matrix.

- Spike recovery (%R) must be with the limits of 75-125 percent. Spike recovery limits do not apply when sample concentration exceeds the spike concentration by a factor of four or more, and data are reported unflagged even if the %R does not meet acceptance criteria.

9.3 Evaluation

Review Form 5 and verify that an MS was prepared and analyzed for each SDG and matrix type, and %R values are within control limits. Recalculate one or more reported %Rs using the following equation:

$$\%R = \frac{(SSR - SR)}{SA} \times 100$$

Where:

SSR = Spiked sample result
SR = Sample result
SA = Spike added

9.4 Action

- o If the spike recovery is > 125 percent and reported sample results are less than IDL, data are acceptable for use and no qualification is necessary.

- o If the spike recovery is > 125 percent or < 75 percent and sample results are greater than IDL, qualify data for all samples of the same matrix in the SDG as estimated (J).

- o If the spike recovery falls within the range of 30-74 percent and sample results are less than IDL, qualify data for these samples as estimated (UJ).

- o If spike recovery results are < 30 percent and sample results are less than IDL, qualify data for these samples as unusable (R).

- o If an MS is not associated with reported sample results, or the MS was performed on a sample from another project or client, all other QC data must be carefully checked when evaluating data.

10.0 Inductively Coupled Plasma Serial Dilution

10.1 Review Items

Form 9 and analytical run log.

NOTE: ICP serial dilutions are not required by EPA Method 200.7.

10.2 Criteria

If the analyte concentration is sufficiently high (concentration in the original sample is minimally a factor of 50 above the IDL), the %D between the sample result and a 5-fold dilution result must be < 10 percent.

10.3 Evaluation

Recalculate the %D for one or more analytes to verify dilution analysis results agree with results reported on Form 9.

$$\%D = \frac{|I - S|}{I} \times 100$$

Where:

I = Initial sample result

S = Serial dilution result (Instrument reading x 5)

10.4 Action

When criteria are not met, qualify associated data as estimated (J). If evidence of negative interference is found, professional judgment is used in qualifying data.

DATA VALIDATION CRITERIA FOR ORGANIC ANALYSES BY GAS CHROMATOGRAPHY/MASS SPECTROMETRY

Refer to Table 10.2 of the QAPjP for minimum laboratory data deliverables for HAZWRAP.

1.0 Validation of Semivolatiles by Gas Chromatography/Mass Spectrometry Analysis

1.1 Technical Holding Times

1.1.1 Review Items

Form 1s, COC forms, laboratory sample receipt form, and case narrative.

1.2 Criteria

- o Aqueous samples for semivolatile organic compounds (SVOCs) analysis must be kept cool (4°C ± 2°C) and extracted within 7 d from sample collection. Analysis must be within 40 d from the date sample extraction was initiated.

- o For cooled (4°C ± 2°C) non-aqueous SVOC samples, extraction must begin within 14 d from sample collection and analysis must be within 40 d from the date sample extraction was initiated.

1.1.3 Evaluation

- o Extraction holding times are established by reviewing sampling dates on signed COC forms with dates of extraction found on Form 1.

- o Analysis holding times are established by comparing the sample extraction date and analysis date found on Form 1.

- o Samples must be received intact at a temperature of 4°C ± 2°C. This information should be located on the laboratory sample receipt form.

1.1.4 Action

- o If samples were not received and maintained at 4°C ± 2°C, use professional judgment to evaluate the possible effect on data. If sample storage temperatures exceeded 20°C, it is recommended that sample results be qualified as estimated (J/UJ).

- o If criteria for holding times are exceeded, qualify positive results as estimated (J) and nondetects as estimated (UJ).

- o If holding times for sample extraction or analysis are grossly exceeded (i.e., by a factor of two or more), qualify positive results as estimated (J) and nondetects as unusable (R).

1.2 Gas Chromatography/Mass Spectrometry Instrument Performance Check (or Tuning)

1.2.1 Review Items

Form 5.

1.2.2 Criteria

- o Samples, blanks, MS/MSDs, and standards must have been injected within the time window specified by the method.

- o Ion abundance criteria listed on Form 5 for the method performed must be met.

- o Tuning frequency and criteria are different for CLP 2/88 and 3/90 revisions, SW-846 Method 8270, and NPDES Methods 525 and 625. Analyses utilizing these methods should be evaluated against stated criteria. All ion abundances must be normalized to m/z 198.

1.2.3 Evaluation

- o Ensure Form 5 is present and complete, and that instrument performance checks were analyzed at the required frequency.

- o Verify the mass spectral listing has been normalized to m/z 198 (peak ion fragment).

1.2.4 Action

- o If environmental and QC samples were not analyzed within the required tuning frequency, use professional judgment in assessing the possible effect on reported data.

- o If the mass listing does not match mass criteria listed on Form 5 or the mass assignment is in error (such as m/z 199 is indicated to be the base peak rather than m/z 198), all associated data must be flagged as unusable (R).

1.3 Initial Calibration

1.3.1 Review Items

Form 6.

1.3.2 Criteria

- o A three- to six-point calibration of semivolatile target compound standards containing surrogates must be analyzed at the beginning of each analytical sequence, or as necessary when continuing calibration acceptance criteria are not met.

- o One calibration standard should be at or near the contract required quantitation limit (PQL) or reporting limit (MDL for non-CLP methods). Standards should not exceed the working range of the GC/MS system.

- o Minimum RRF criteria must be ≥ 0.05.

- o The percent relative standard deviation (RSD) for RRFs in the initial calibration must be $\leq$ 30 percent.

1.3.3 Evaluation

- o Verify that the correct number and concentrations of standards were used for initial calibration.

- o Ensure standards were analyzed within the required frequency of the associated instrument performance check.

- o Ensure RRFs for initial calibration standards for all target compounds and surrogates are ≥ 0.050.

- o Ensure all initial calibration percent RSDs are ≤ 30 percent for compounds in the calibration curve.

1.3.4 Action

- o If the number and concentrations of calibration standards required by the method were not analyzed, samples associated with that calibration curve must be evaluated carefully to determine the usability of data.

- o If any compound has a RSD > 30 percent and the RRF is ≥ 0.050, positive results for that compound must be flagged as estimated (J) and nondetects should be qualified using professional judgment. For example, the following qualifications are recommended:

  - If the percent RSD is > 30 percent but ≤ 50 percent, and the RRF is ≥ 0.050, qualify positive results (J). Do not qualify nondetects.

  - If the percent RSD is > 50 percent but ≤ 80 percent, and the RRF is ≥ 0.050, qualify positive results (J) and nondetects (UJ).

  - If the percent RSD is > 80 percent, and RRF is ≥ 0.05, qualify positive results (J) and nondetects (R).

- o If any initial calibration RRF is < 0.050, all positive results for that compound must be flagged as estimated (J) and nondetects for that compound qualified as unusable (R).

1.4 Continuing Calibration

1.4.1 Review Items

Form 5, Form 6, and Form 7.

1.4.2 Criteria

- o The continuing calibration standard must be performed immediately after the system performance check (decafluorotriphenylphosphine tune) at the beginning of each analytical sequence and within the required tuning frequency.

- o The minimum continuing calibration RRF for compounds (target compounds and surrogates) is ≥ 0.050.

- o Continuing calibration %D between the initial calibration average RRF and the continuing calibration RRF must be within the ± 25 percent window for all compounds.

1.4.3 Evaluation

- o Verify the continuing calibration standard was performed at the required frequency and order by checking Form 5.

- o Verify the continuing calibration was compared to the correct initial calibration by checking Form 6 with Form 7.

- o Verify RRFs and %D for all compounds are within specifications.

1.4.4 Action

- o If the continuing calibration RRF is < 0.050, qualify positive results as estimated (J) and nondetected semivolatile target compounds as unusable (R).

- o If the %D is outside the ± 25 percent criterion and the continuing calibration RRF is ≥ 0.050, qualify detected and nondetected compounds as estimated (J/UJ).

1.5 Laboratory Blanks

1.5.1 Review Items

Form 1 and Form 4.

1.5.2 Criteria

- o No contaminants should be found in blanks.

- o A method blank must be analyzed on each GC/MS system used to analyze the reported sample group.

1.5.3 Evaluation

- o Review Form 1s for associated laboratory blanks to determine the presence of target and nontarget compounds in the blanks.

- o Ensure that a method blank has been reported per matrix, per concentration level, for each extraction batch (at a frequency of 1 to 20 extracted samples, or less), and for each GC/MS system used to analyze SVOC samples. The Method Blank Summary (Form 4) should be used to identify samples associated with each method blank.

1.5.4 Action

- o If a compound is found in a blank but not found in the associated sample, no action is taken.

- If a compound is found in a blank and the associated sample, the following two rules (5X and 10X) apply:

  - The 10X rule applies to common phthalate laboratory contaminants.

    - When concentration of the compound in the sample is greater than or equal to PQL or the reporting limit, but < 10X the highest concentration found in a laboratory blank, consider the result as a nondetect and flag it with a (U).

    - When concentration of the compound in the sample is less than PQL or the reporting limit, and < 10X the highest concentration found in a laboratory blank, report the result at PQL or the reporting limit with a (U) qualifier.

    - When concentration of the compound in the sample is ≥ 10X the highest concentration found in a laboratory blank, the result is considered as positive, and no flag is required.

  - The 5X rule applies to compounds other than the common phthalate laboratory contaminants listed previously.

    - When concentration of the compound in the sample is greater than or equal to PQL or the reporting limit but < 5X the highest concentration found in a laboratory blank, consider the result as a nondetect and flag it with a (U).

    - When concentration of the compound in the sample is less than PQL or the reporting limit and < 5X the highest concentration found in a laboratory blank, report the result at PQL or the reporting limit with a (U) qualifier.

    - When concentration of the compound in the sample is ≥ 5X the highest concentration found in a laboratory blank, consider the result as positive, and no flag is required.

- If inordinate amounts of other target compounds and/or TICs are found in any blank, this should be noted in the validation report.

- o If no method blank was extracted and analyzed for each set of samples (or at a frequency of 1 per 20 or less), or if the method blank was not run on the same GC/MS system as the samples, associated data must be assessed using professional judgment.

- o The same consideration given to target compounds should also be given to TICs found in both the sample and associated blank(s) (see Section 1.11 for TIC guidance).

1.6 Equipment Rinseates and ASTM Type II Source Water Check Samples

1.6.1 Review Items

Results for equipment rinseates and ASTM Type II source water check samples associated with the collection of environmental samples and decontamination of sampling equipment.

1.6.2 Criteria

Ideally, no target analytes should be present in equipment rinseates and ASTM Type II source water check samples.

1.6.3 Evaluation

Review associated equipment rinseate and ASTM Type II source water results (Form 1s) to determine if contamination has resulted due to sample collection and equipment decontamination procedures.

1.6.4 Action

Use professional judgment when qualifying sample results based on equipment rinseate and ASTM Type II source water results. All equipment rinseate and ASTM Type II source water check samples collected during the sampling event or field effort may need to be reviewed to determine if trends in contamination are occurring. For example, if 1 compound is detected in 80 percent of environmental samples, but only appears in 5 percent of the associated equipment rinseate samples, this is probably indicative of environmental contamination and sample results should not be qualified.

1.7 Surrogate Spikes

1.7.1 Review Items

Form 2.

1.7.2 Criteria

- o The number and concentration of surrogate compounds specified in the method performed must be added to all samples and blanks to measure their recovery in sample and blank matrices.

- o Surrogate spike recoveries for the method performed must be within acceptance limits specified on the laboratory Form 2.

1.7.3 Evaluation

- o Review Form 2 to verify that surrogate recoveries for samples and blanks are within acceptance limits.

- o Verify that method requirements for re-analysis of samples based on surrogate recovery were followed.

1.7.4 Action

- o If the method performed requires less than three surrogates per fraction (acid and base/neutral), professional judgment must be used to assess data.

  - If two or more surrogates in either SVOC fraction (base/neutral or acid) have a recovery greater than the upper QC limit, that affected fraction of compounds with positive results will be qualified as estimated (J) and nondetects will not be qualified.

  - If two or more surrogates in either SVOC fraction have a recovery greater than or equal to ten percent, but less than the lower acceptance limit, that affected fraction of compounds will be qualified as estimated (J/UJ).

- o If any surrogate spike recovery is less than ten percent, detected semivolatile target compounds should be flagged as estimated (J) and nondetect semivolatile target compounds should be qualified as unusable (R).

1.8 Matrix Spike/Matrix Spike Duplicate

1.8.1 Review Items

Form 3.

1.8.2 Criteria

- o MS and MSD samples must be analyzed at a frequency of at least 1 MS and MSD per 20 samples of similar matrix.

- o Spike recoveries should be within method-specific limits provided on Form 3.

- o RPD between MS and MSD recoveries must be within limits provided on Form 3.

1.8.3 Evaluation

- o Verify that MS and MSD samples were analyzed at the required frequency and results are provided for each sample matrix.

- o Ensure results for MS/MSD %R and RPD are within limits.

1.8.4 Action

No action is taken on MS/MSD data alone. Professional judgment must be used to evaluate MS/MSD results in conjunction with other QC criteria to determine if qualifications are necessary.

1.9 Laboratory Control Samples (If required by method)

1.9.1 Review Items

Form 3 and Form 1 for LCS.

1.9.2 Criteria

- o LCSs are analyzed at a frequency of 1 per 20 samples per SDG.
- o The LCS must be prepared and analyzed with samples reported in the SDG.
- o LCS %Rs must be within acceptance limits provided on Form 3.

1.9.3 Evaluation

Verify that an LCS was analyzed at the required frequency and results are within acceptance limits specified on Form 3.

1.9.4 Action

If LCS criteria are not met, professional judgment must be used to assess data for qualification. The following guidance is suggested for qualifying sample data for which the associated LCS does not meet required criteria.

- o If LCS recovery is greater than the upper acceptance limit, positive sample results for affected compound(s) should be qualified as estimated (J). Nondetects do not require qualification.
- o If LCS recovery is less than the lower acceptance limit, associated detected target compounds should be qualified estimated (J) and all nondetects should be qualified as unusable (R).

1.10 Internal Standard Area Performance

1.10.1 Review Items

Form 8.

1.10.2 Criteria

- o IS area counts must not vary by more than a factor of two (-50 percent to +100 percent) from the associated continuing calibration standard.

- o RT of the IS must not vary more than ± 30 s from the RT of the associated continuing calibration standard.

1.10.3 Evaluation

- o Verify that all RT and IS areas are within required criteria.

- o If two analyses were performed for a particular fraction, the validator must determine which are the best data to report. Considerations should include:

  - Magnitude and direction of the IS area shift.

  - Magnitude and direction of the IS RT shift.

  - Technical holding times.

  - Comparison of values of the target compounds in each fraction.

  - Comparison of other QC data.

1.10.4 Action

- o If an IS area count for a sample or blank is outside - 50 percent or + 100 percent of the area of the associated standard:

- Positive results for compounds quantitated using that IS should qualified as estimated (J).

- Nondetected compounds quantitated using an IS area count > 100 percent should not be qualified.

- Nondetected compounds quantitated using an IS area count < 50 percent are reported at the associated sample quantitation limit as estimated (UJ).

o If extremely low area counts are reported, or if performance exhibits a major abrupt drop-off, severe loss of sensitivity is indicated. Nondetected target compounds should be qualified as unusable (R).

o If an IS RT varies > 30 s from the associated standard, professional judgment must used. Validators may determine that positive results should be flagged as estimated (J), and nondetected semivolatile compounds for that IS should be qualified as unusable (R).

1.11 Tentatively Identified Compounds (if required)

1.11.1 Review Items

Form 1s for samples and blanks, and Form 4.

1.11.2 Criteria

o For each sample, the laboratory must conduct a mass spectral search of the NIST library and report the possible identity for SVOC fraction peaks that are not surrogate spikes, ISs, or TCLs, but have area or height > 10 percent (> 50 percent for the CLP Low Concentration Water method) of the area or height of the nearest IS.

o TIC results are reported for each sample on the Organic Analysis Data Sheet (Form 1). The number of TICs to be reported is specified in the analytical method or QAPP.

1.11.3 Evaluation

- o Form 1s for laboratory blanks should be examined to verify that TICs reported in associated samples are not found in blanks. This is accomplished by comparing compound RTs reported on Form 1s for samples and blanks.

- o The reviewer should be aware of common laboratory artifacts/contaminants and their sources (e.g., aldol condensation products, solvent preservatives, and reagent contaminants). These may be present in blanks and not reported as sample TICs:

  - Common laboratory contaminants [phthalates (m/z 149) at levels < 100 μg/L or 4000 μg/Kg].

  - Solvent preservatives, such as cyclohexene which is a methylene chloride preservative. Related by-products include cyclohexanone, cyclohexenone, cyclohexanol, cyclohexenol, chlorocyclohexene, and chlorocyclohexanol.

1.11.4 Action

- o TIC results should be flagged (NJ), tentatively identified, with approximated concentrations.

- o If the TIC is not found in any blanks, but is a suspected artifact of common laboratory contamination, the result may be qualified as unusable (R).

- o TIC results not sufficiently above the level in the blank should not be reported. (Dilutions and sample size must be taken into account when comparing the amounts present in blanks and samples.)

- o Similar isomers may be reported as a total number.

2.0 Validation of Volatiles by Gas Chromatography/Mass Spectrometry Analysis

2.1 Technical Holding Times

2.1.1 Review Items

Form 1s, COC forms, laboratory sample receipt form, and case narrative.

2.1.2 Criteria

- o Aqueous samples for VOC analysis must be kept cool (4°C ± 2°C) and acid preserved to a pH of 2 or below. Analysis must be within 14 d from the date of sample collection.

- o For cooled (4°C ± 2°C) non-aqueous VOC samples, analysis must be within 14 d from the date sample collection.

- o Aqueous samples that have not been preserved to a pH of 2 or below must be analyzed within 7 d of sample collection.

2.1.3 Evaluation

- o Analysis holding times are established by comparing the sample analysis date with the collection date. This review is accomplished by using information from the Form 1 and COC form.

- o Samples must be received intact at a temperature of 4°C ± 2°C. This information should be located on the laboratory sample receipt form.

2.1.4 Action

- o If samples were not received and maintained at 4°C ± 2°C, use professional judgment to evaluate the possible effect on data. The following guidelines are recommended for qualification of volatile organic results based on sample temperature:

- If laboratory records indicate that samples were received and/or maintained between 7 and 15°C, qualify results as estimated (J/UJ).

- If laboratory records indicate that samples were received and/or maintained at > 15°C, nondetected results may be rejected (R). Positive detects are qualified (J), estimated.

o If criteria for holding times are exceeded, qualify positive results as estimated (J) and nondetects as estimated (UJ).

o If holding times for sample analysis are grossly exceeded (i.e., by a factor of two or more), qualify positive results as estimated (J) and nondetects as unusable (R).

2.2 Gas Chromatography/Mass Spectrometry Instrument Performance Check (or Tuning)

2.2.1 Review Items

Form 5.

2.2.2 Criteria

o Samples, blanks, MS/MSDs, and standards must have been injected within the time window specified by the method.

o Ion abundance criteria listed on Form 5 for the method performed must be met.

o Tuning frequency and criteria are different for CLP 2/88 and 3/90 revisions, SW-846 Method 8240, and NPDES Methods 524.2 and 624. Analyses utilizing these methods should be evaluated against stated criteria. All ion abundances must be normalized to m/z 95.

2.2.3 Evaluation

o Ensure Form 5 is present and complete, and that instrument performance checks were analyzed at the required frequency.

- o Verify the mass spectral listing has been normalized to m/z 95 (peak ion fragment).

2.2.4 Action

- o If environmental and QC samples were not analyzed within the required tuning criteria frequency, use professional judgment in assessing the possible effect on reported data.

- o If the mass listing does not match mass criteria listed on Form 5 or the mass assignment is in error (such as m/z 96 is indicated to be the base peak rather than m/z 95), all associated data must be flagged as unusable (R).

2.3 Initial Calibration

2.3.1 Review Items

Form 6.

2.3.2 Criteria

- o A three- to five-point calibration of volatile target compounds containing surrogates must be analyzed at the beginning of each analytical sequence, or as necessary when continuing calibration acceptance criteria are not met.

- o One calibration standard should be at or near PQL or the reporting limit (MDL for non-CLP methods). Standards should not exceed the working range of the GC/MS system.

- o Minimum RRF criteria must be ≥ 0.05.

- o The percent RSD for RRFs in the initial calibration must be ≤ 30 percent.

2.3.3 Evaluation

- o Verify that the correct number and concentrations of standards were used for initial calibration.

- Ensure standards were analyzed within required frequency of the associated instrument performance check.

- Ensure RRFs for initial calibration standards for all target compounds and surrogates are ≥ 0.050.

- Ensure all initial calibration percent RSDs are ≤ 30 percent for compounds in the calibration curve.

2.3.4 Action

- If the number and concentration of required calibration standards according to the method were not analyzed, samples associated with that calibration curve must be evaluated carefully to determine the usability of data.

- If any compound has a percent RSD > 30 percent and RRF is ≥ 0.050, positive results for that compound must be flagged as estimated (J) and nondetects should be qualified using professional judgment. For example, the following qualifications are recommended:

  - If the percent RSD is > 30 percent but ≤ 50 percent, and the RRF is ≥ 0.050, qualify positive results (J). Do not qualify nondetects.

  - If the percent RSD is > 50 percent but ≤ 80 percent, and the RRF is ≥ 0.050, qualify positive results (J) and nondetects (UJ).

  - If the percent RSD is > 80 percent, and RRF is ≥ 0.05, qualify positive results (J) and nondetects (R).

- If any initial calibration RRF is < 0.050, all positive results for that compound must be flagged as estimated (J) and nondetects for that compound qualified as unusable (R).

2.4 Continuing Calibration

2.4.1 Review Items

Form 5, Form 6, and Form 7.

2.4.2 Criteria

- The continuing calibration standard must be performed immediately after the system performance check (bromofluorobenzene tune) at the beginning of each analytical sequence and within the required tuning frequency.

- The minimum continuing calibration RRF for compounds (TCLs and surrogates) is ≥ 0.050.

- Continuing calibration %D between the initial calibration average RRF and the continuing calibration RRF must be within the ± 25 percent window for all compounds. For data generated by the CLP Low Concentration Water method, %D between the initial calibration average RRF and the continuing calibration RRF must be within ± 30 percent.

2.4.3 Evaluation

- Verify the continuing calibration standard was performed at the required frequency by checking Form 5.

- Verify the continuing calibration was compared to the correct initial calibration by checking Form 6 with Form 7.

- Verify RRFs and %D for all compounds are within limits.

2.4.4 Action

- If the continuing calibration RRF is < 0.050, qualify positive results as estimated (J) and nondetected volatile target compounds as unusable (R).

- If the %D is outside the ± 25 percent criterion and the continuing calibration RRF is ≥ 0.050, positive results must be flagged as estimated (J) and nondetect volatile target compounds (UJ).

2.5 Laboratory and Trip Blanks

2.5.1 Review Items

Form 1, Form 4, COC form, and results for associated trip blanks. (Correlations between trip blanks and environmental samples in the SDG must also be provided.)

2.5.2 Criteria

- No contaminants should be found in blanks.

- A method blank must be analyzed on each GC/MS system used to analyze the reported sample group.

- If required by the method (i.e., CLP Low Concentration Water and CLP SOW OLM02.1), a storage blank must be prepared upon receipt of the first samples from the SDG, and stored with samples until analysis. The storage blank must be analyzed once per SDG.

2.5.3 Evaluation

- Review results (Form 1s) for associated laboratory and trip blanks to determine the presence of target and non-target compounds in the blanks.

- Ensure that a method blank has been reported per matrix, per concentration level, for each analytical batch (at a frequency of 1 per 20 samples, 1 per 12 hours of analyses, or less), and for each GC/MS system used to analyze VOC samples. The Method Blank Summary (Form 4) should be used to identify samples associated with each method blank.

- Review COC forms to ensure that a trip blank has been included in each cooler containing samples for VOC analysis.

- Verify that a storage blank (if required by the method performed) has been analyzed and included with each SDG and that storage blanks are free of contamination.

2.5.4 Action

- If a compound is found in a laboratory or trip blank but not found in the associated sample, no action is taken.

- If a compound is found in a laboratory or trip blank and the associated sample, the following two rules (5X and 10X) apply:

  - The 10X rule applies to common laboratory contaminants (acetone, methylene chloride, and 2-butanone).

    - When concentration of the compound in the sample is greater than or equal to PQL or the reporting limit, but < 10X the highest concentration found in an associated laboratory or trip blank, consider the result as a nondetect and flag it with a (U).

    - When concentration of the compound in the sample is less than PQL or the reporting limit, and < 10X the highest concentration found in an associated laboratory or trip blank, report the result at PQL or the reporting limit with a (U) qualifier.

    - When concentration of the compound in the sample is ≥ 10X the highest concentration found in an associated laboratory or trip blank, the result is considered as positive, and no flag is required.

  - The 5X rule applies to compounds other than the VOC common laboratory contaminants listed previously.

    - When concentration of the compound in the sample is greater than or equal to PQL or the reporting limit, but < 5X the highest concentration found in an associated laboratory or trip blank, consider the result as a nondetect and flag it with a (U).

- When concentration of the compound in the sample is less than PQL or the reporting limit and < 5X the highest concentration found in an associated laboratory or trip blank, report the result at PQL or the reporting limit with a (U) qualifier.

- When concentration of the compound in the sample is ≥ 5X the highest concentration found in an associated laboratory or trip blank, consider the result as positive, and no flag is required.

- If inordinate amounts of other target compounds and/or TICs are found in any blank, this should be noted in the validation report. TICs found in blanks should be qualified by the "5X rule" in associated samples and qualified as unusable (R).

- If laboratory blanks were not analyzed at the required frequency, or if the laboratory blank was not run on the same GC/MS system as samples, associated data must be assessed using professional judgment.

- The same consideration given to target compounds should also be given to TICs found in both the sample and associated blank(s) (see Section 2.11 for TIC guidance).

2.6 Equipment Rinseates and ASTM Type II Source Water Check Samples

2.6.1 Review Items

Form 1s for equipment rinseates and ASTM Type II source water check samples associated with the collection of environmental samples and decontamination of sampling equipment.

2.6.2 Criteria

Ideally, no target analytes should be present in equipment rinseates and ASTM Type II source water check samples.

2.6.3 Evaluation

- o Review associated equipment rinseate and ASTM Type II source water check sample results to determine if contamination has resulted due to sample collection and equipment decontamination procedures.

- o All equipment rinseate and ASTM Type II source water check samples collected during the sampling event or field effort may need to be reviewed to determine if trends in contamination are occurring. For example, if 1 compound is detected in 80 percent of environmental samples, but only appears in 5 percent of the associated equipment rinseate samples, this is probably indicative of environmental contamination and sample results should not be qualified.

2.6.4 Action

- o Use professional judgment when qualifying sample results based on equipment rinseate and ASTM Type II source water check sample results. If contamination is present in these field QC samples, associated data must be carefully evaluated to determine whether there is an inherent variability in the data set, or if the problem is an isolated occurrence not affecting other data.

2.7 Surrogate Spikes or System Monitoring Compounds

2.7.1 Review Items

Form 2.

2.7.2 Criteria

- o The number and concentration of surrogate compounds specified in the method performed must be added to all samples and blanks to measure their recovery in sample and blank matrices.

- o Acceptance limits for surrogate spike recoveries for the method performed must be specified on the laboratory Form 2.

2.7.3 Evaluation

- o Review Form 2 to verify that surrogate recoveries for samples and blanks are within acceptance limits.

- o Verify that method requirements for re-analysis of samples based on surrogate recovery were followed.

2.7.4 Action

- o If a surrogate in the volatile sample has a recovery greater than the upper acceptance limit, detected volatile compounds are qualified as estimated (J) and nondetects are not qualified.

- o If a surrogate in the volatile sample has a recovery greater than or equal to ten percent, but less than the lower acceptance limits, qualify detected and nondetected compounds as estimated (J/UJ).

- o If any surrogate spike recovery is less than ten percent, detected volatile target compounds should be flagged as estimated (J) and nondetect volatile target compounds should be qualified as unusable (R).

2.8 Matrix Spike/Matrix Spike Duplicate

2.8.1 Review Items

Form 3.

2.8.2 Criteria

- o MS and MSD samples must be analyzed at a frequency of at least 1 MS and MSD per 20 samples of similar matrix.

- o MS recoveries should be within method-specific limits provided on Form 3.

- o RPD between MS and MSD recoveries should be within acceptance limits provided on Form 3.

2.8.3 Evaluation

- o Verify that MS and MSD samples were analyzed at the required frequency and results are provided for each sample matrix.

- o Ensure results for MS/MSD %R and RPD are within acceptance limits.

2.8.4 Action

No action is taken on MS/MSD data alone. Professional judgment must be used to evaluate MS/MSD results in conjunction with other QC criteria to determine if qualifications are necessary.

2.9 Laboratory Control Samples (If required)

2.9.1 Review Items

Form 3 and Form 1 for LCS.

2.9.2 Criteria

- o LCSs are analyzed at a frequency of one per SDG.

- o The LCS must be prepared and analyzed with samples reported in the SDG.

- o LCS %Rs must be within acceptance limits listed on Form 3.

2.9.3 Evaluation

Verify that LCS samples were analyzed at the required frequency and results are within acceptance limits.

2.9.4 Action

If LCS criteria are not met, professional judgment must be used to assess data for qualification. The following guidance is suggested for qualifying sample data for which the associated LCS does not meet required criteria.

- o If LCS recovery is greater than the upper acceptance limit, positive sample results for affected compounds should be qualified as estimated (J) and nondetects require no qualification.

- o If LCS recovery is less than the lower acceptance limit, positive results for affected compounds should be qualified estimated (J) and nondetects should be qualified as unusable (R).

2.10 Internal Standard Area and Retention Time Performance

2.10.1 Review Items

Form 8.

2.10.2 Criteria

- o IS area counts must not vary by more than a factor of two (-50 percent to +100 percent) from the associated daily calibration standard. (For the CLP Low Concentration Water method, IS area counts must not vary by more than ± 40 percent from the associated calibration standard).

- o RT of the IS must not vary more than ± 30 s (± 20 s for the CLP Low Concentration Water method) from the RT of the associated calibration standard.

2.10.3 Evaluation

- o Verify that all RT and IS areas are within required criteria.

- o If two analyses were performed for a particular fraction, the validator must determine which are the best data to report. Considerations should include:

  - Magnitude and direction of the IS area shift.

  - Magnitude and direction of the IS RT shift.

  - Technical holding times.

  - Comparison of values of target compounds reported in each fraction.

  - Comparison of other QC data.

2.10.4 Action

- o If an IS area count for a sample or blank is outside - 50 percent or + 100 percent (± 40 percent for the CLP Low Concentration Water method) of the area of the associated standard:

  - Positive results for compounds quantitated using that IS should qualified as estimated (J).

  - Nondetected compounds quantitated using an IS area count > 100 percent (> 40 percent for the CLP Low Concentration Water method) should not be qualified.

  - Nondetected compounds quantitated using an IS area count < 50 percent (< 40 percent for the CLP Low Concentration Water method) are reported as the associated sample quantitation limit and qualified as estimated (UJ).

- o If extremely low area counts are reported, or if performance exhibits a major abrupt drop-off, severe loss of sensitivity is indicated. Nondetected target compounds should be qualified as unusable (R).

- o If an IS RT varies > 30 s (or >20 s for the Low Concentration Water SOW) from the associated standard, professional judgment must used. Validators may determine that positive results should be flagged as estimated (J), and nondetected semivolatile compounds for that IS should be qualified as unusable (R).

2.11 Tentatively Identified Compounds (if required)

2.11.1 Review Items

Form 1s for samples and blanks, and Form 4.

2.11.2 Criteria

- o For each sample, the laboratory must conduct a mass spectral search of the NIST library and report the possible identity for the VOC fraction peaks that are not surrogate spikes, ISs, or TCLs, but have areas or heights greater than ten percent of the area or height of the nearest IS. (For the CLP Low Concentration Water method, major ions must be > 25 percent relative intensity in the reference spectrum).

- o TIC results are reported for each sample on the Organic Analyses Data Sheet (Form 1). The number of TICs to be reported is specified in the analytical method or QAPP.

2.11.3 Evaluation

- o Form 1s for samples and laboratory blanks should be examined to verify that TICs reported in samples are not found in blanks. This is accomplished by comparing compound RTs reported on Form 1s for samples and blanks.

- o The reviewer should be aware of common laboratory artifacts/contaminants and their sources (e.g., carbon dioxide, diethyl ether, hexane, certain freons, aldol condensation products, solvent preservatives, and reagent contaminants). These may be present in blanks and not reported as sample TICs.

2.11.4 Action

- o TIC results should be flagged (NJ), tentatively identified, with approximated concentrations.

- o If the TIC is not found in any blanks, but is a suspected artifact of common laboratory contamination, the result may be qualified as unusable (R).

- o TIC results not sufficiently above the level in the blank should not be reported. (Dilutions and sample size must be taken into account when comparing the amounts present in blanks and samples.)

- o Similar isomers may be reported as a total number.

DATA VALIDATION CRITERIA FOR ORGANIC ANALYSIS VIA GAS CHROMATOGRAPHY

Refer to Table 10.2 of the QAPP for minimum laboratory data deliverables for HAZWRAP.

1.0 Validation of Pesticides and Polychlorinated Biphenyls by Gas Chromatography Analysis

1.1 Technical Holding Time

1.1.1 Review Items

Form 1, Form 10A and 10B, COC forms, case narrative, and laboratory sample receipt form.

1.1.2 Criteria

- For pesticides and PCBs in cooled (4°C ± 2°C) water samples, the holding time is 7 d from time of sample collection to extraction, and 40 d from sample extraction to analysis.

- For pesticides and PCBs in cooled (4°C ± 2°C) non-aqueous samples, the holding time is 14 d from time of sample collection to extraction, and 40 d from sample extraction to analysis.

1.1.3 Evaluation

- For sample extraction, compare the sample collection date on the COC form with the date of extraction on Form 1.

- For sample analysis, compare the dates of extraction and analysis reported on the Form 1. For samples requiring second-column confirmation, refer to Forms 10A and 10B for dates of analysis on both columns.

- Verify that samples were received intact at a temperature of 4°C ± 2°C. This information should be located on the laboratory sample receipt form.

1.1.4 Action

- o If samples were not received and maintained at 4°C ± 2°C, use professional judgment to evaluate the possible effect on data.

- o If criteria for holding times are exceeded, qualify positive results as estimated (J), and nondetects as estimated (UJ).

- o If holding times for sample extraction or analysis are grossly exceeded (i.e., by a factor of two or more), qualify positive results as estimated (J), and nondetects as unusable (R).

- o Use professional judgment in qualifying results for detected compounds when primary column analysis is performed within holding time, but second-column confirmation analysis exceeds holding time requirements.

1.2 Initial Calibration

1.2.1 Review Items

Form 6D, Form 6E, and Form 6F.

1.2.2 Criteria

- o A three- to five-point calibration of pesticide/PCB target compound standards containing surrogates must be analyzed at the beginning of each analytical sequence, or as necessary when continuing calibration acceptance criteria are not met.

- o Standards must be analyzed on each GC column and instrument used for analysis.

- o One calibration standard should be at or near PQL or the reporting limit (MDL for non-CLP methods), and standards should not exceed the working range of the GC system.

- o For external standard calibration: If the calibration factor RSD is constant over the working range (i.e., < 10-20 percent RSD), the average calibration factor may be used for sample quantitation in place of a calibration curve.

NOTE: The acceptable percent RSD for calibration factors is specified by the analytical method performed.

- For IS calibration: If the response factor RSD is constant over the working range (i.e., < 10-20 percent RSD), the average response factor can be used for sample quantitation.

NOTE: The acceptable percent RSD for response factors is specified by the analytical method performed.

1.2.3 Evaluation

- Verify that the correct number and concentration of standards were used for initial calibration, and that standards were analyzed on each column and instrument used for sample analysis.

- If the external standard calibration method was used for sample quantitation, ensure that the calibration factor percent RSD listed on Forms 6E and 6F meets method requirements.

- If the IS calibration method was used for sample quantitation, ensure that the response factor percent RSD listed on Forms 6E and 6F meets method requirements.

1.2.4 Action

- If the number and concentrations of calibration standards required by the method were not analyzed, samples associated with that calibration curve must be carefully evaluated to determine the usability of data.

- If the percent RSD linearity criteria are not met for compounds being quantified, qualify all associated positive quantitative results as estimated (J). When the percent RSD is grossly exceeded (i.e., > 50 percent), nondetects may be qualified as estimated (UJ).

1.3 Continuing Calibration

1.3.1 Review Items

Form 6D, Form 7, and Form 8.

1.3.2 Criteria

- o A continuing calibration standard must be analyzed at least daily to verify the calibration curve, calibration factors, or response factors. The concentration level and frequency of analysis of the continuing calibration standard is specified in the method performed.

- o The %D between the continuing calibration standard response for any parameter and the predicted response must be within limits specified by the method performed. (For methods SW-8080 and EPA 608, criteria are ± 15 %D).

1.3.3 Evaluation

- o Check Form 8 to verify that continuing calibration standards were analyzed daily and at the proper frequency and concentration.

- o Verify that RTs for target compounds in the continuing calibration standard are within RT windows established by the initial calibration listed on Form 6.

- o Verify that the continuing calibration standard %D from the initial calibration is within method-specified limits.

1.3.4 Action

- o If the continuing calibration standard was not analyzed as required, professional judgment must be used to determine if data should be qualified.

- o If continuing calibration standards do not fall within RT windows, associated sample results should be carefully evaluated. All samples injected after the last in-control standard are potentially affected.

- o If the %D exceeds criteria for the compound(s) being quantified, qualify all associated positive results as estimated (J). Nondetects should be qualified as estimated (UJ) when the difference exceeds 50 percent.

1.4 Laboratory Blanks

1.4.1 Review Items

Form 1 and Form 4.

1.4.2 Criteria

- o No contaminants should be present in laboratory blanks.

- o A method blank must be analyzed for each 20 samples of similar matrix in each SDG or whenever a sample extraction procedure is performed. A method blank must be analyzed on each GC column and instrument used to analyze the reported sample group.

1.4.3 Evaluation

- o Review the results of all associated laboratory blanks, Form 1 and Form 4, to evaluate the presence of target pesticides/PCBs.

- o Verify that a method blank analysis has been reported per SDG, per matrix, per concentration level and extraction batch, for each GC system used to analyze samples.

1.4.4 Action

- o If a target pesticide or PCB is found in a laboratory blank but not in the sample(s), no qualification is required.

- o Any pesticide or PCB compound detected in the sample and also detected in an associated laboratory blank is qualified if the sample concentration is < 5X the blank concentration:

- If the sample concentration is greater than or equal to PQL or the reporting limit, the result is considered a nondetect and qualified (U).

- If the sample concentration is less than PQL or the reporting limit, report the result at the PQL or reporting limit with a (U) qualifier.

o If the sample result is > 5X the blank result and greater than PQL or the reporting limit, the sample result is not qualified.

1.5 Equipment Rinseates and ASTM Type II Source Water Check Samples

1.5.1 Review Items

Results for equipment rinseates and ASTM Type II source water check samples associated with the collection of environmental samples and decontamination of sampling equipment.

1.5.2 Criteria

Ideally, no target analytes should be present in equipment rinseates and ASTM Type II source water check samples.

1.5.3 Evaluation

Review associated equipment rinseate and ASTM Type II source water results (Form 1s) to determine if contamination has resulted because of sample collection and equipment decontamination procedures.

1.5.4 Action

Use professional judgment when qualifying sample results based on equipment rinseate and ASTM Type II source water results. All equipment rinseate and ASTM Type II source water check samples collected during the sampling event or field effort may need to be reviewed to determine if trends in contamination are occurring.

1.6 Surrogate Spikes

1.6.1 Review Items

Form 2 and Form 8.

1.6.2 Criteria

- o Surrogate spikes are added to all samples, standards, blanks, and MSs to measure their recovery in sample and blank matrices. The number of surrogates and compounds to be used is specified in the analytical method performed.

- o Surrogate recoveries must be within acceptance limits listed on Form 2.

- o Surrogate RTs reported on Form 8 must be within calculated RT windows listed on Forms 6D and 6F.

- o Use professional judgment when surrogate recoveries in samples are not within acceptance limits for both GC column analyses. Qualification in this case should be based on the number of surrogate compounds outside recovery criteria and the magnitude of the exceedance of criteria.

1.6.3 Evaluation

- o Review Form 2 to verify that surrogate recoveries in samples and blanks are within acceptance limits.

- o Review Form 8 to verify that surrogate RTs are within calculated RT windows listed on Forms 6D and 6F.

1.6.4 Action

- o If a surrogate recovery is greater than the upper QC limit, qualify associated detected compound data as estimated (J). Nondetected compounds do not require qualification.

- o If a surrogate recovery is greater than or equal to ten percent, but less than the lower QC limit, qualify associated detected compound data as estimated (J), and nondetected compound data as estimated (UJ).

- o If any surrogate recovery is less than ten percent, detected target compounds must be qualified as estimated (J), and nondetects qualified as unusable (R).

1.7 Matrix Spikes/Matrix Spike Duplicates

1.7.1 Review Items

Form 3 and QC check sample results (if required).

1.7.2 Criteria

- o MS/MSD samples are analyzed at a frequency of at least 1 MS and MSD per 20 samples of similar matrix.

- o MS recoveries should be within control limits provided on Form 3.

- o RPD between MS and MSD recoveries should be within control limits provided on Form 3.

- o If required by the method, a QC check sample must be analyzed for compounds that do not meet the MS/MSD %Rs listed on Form 3.

1.7.3 Evaluation

- o Verify that MS and MSD samples were analyzed at the required frequency and that results are provided for each sample matrix.

- o Inspect MS/MSD results reported on Form 3 and verify that the results for recovery and RPD are within control limits.

- o If required by the method, ensure that a QC check sample was analyzed for MS compounds not meeting acceptance criteria.

1.7.4 Action

No action is taken on MS/MSD data alone. However, using the MS/MSD results in conjunction with other QC criteria, including QC check sample results, some qualification of the data may be required.

1.8 Laboratory Control Samples (If required by method)

1.8.1 Review Items

Form 3 and Form 1 for LCS.

1.8.2 Criteria

- o LCSs are analyzed at a frequency of 1 per 20 samples per SDG.
- o The LCS must be prepared and analyzed with the samples reported in the SDG.
- o LCS %Rs must be within acceptance limits provided on Form 3.

1.8.3 Evaluation

Verify that an LCS was analyzed at the required frequency and results are within acceptance limits specified on Form 3.

1.8.4 Action

If LCS criteria are not met, professional judgment must be used to assess the data for qualification. The following guidance is suggested for qualifying sample data for which the associated LCS does not meet required criteria:

- o If LCS recovery is greater than the upper acceptance limit, positive sample results for the affected compound(s) should be qualified as estimated (J). Nondetects do not require qualification.

- o If LCS recovery is less than the lower acceptance limit, associated detected target compounds should be qualified estimated (J) and all nondetects should be qualified as unusable (R).

1.9 Pesticide Cleanup Checks (If required)

1.9.1 Review Items

Form 9A and Form 9B.

1.9.2 Criteria

- o Florisil Cartridge Cleanup

  - The florisil cleanup procedure significantly reduces matrix interferences caused by polar compounds. Every lot number of florisil or florisil cartridges used for sample cleanup should be checked by spiking with selected pesticide compounds and a highly polar compound such as 2,4,5-trichlorophenol.

  - The lot of florisil cartridges is acceptable if recoveries for all pesticides and surrogates spiked are within 80-120 percent, and the recovery of 2,4,5-trichlorophenol is < 5 percent.

- o Gel Permeation Chromatography

  - Gel Permeation Chromatography (GPC) is used for the cleanup of samples that contain high molecular weight components that will interfere with analysis.

  - The GPC unit should be checked by spiking with the pesticide matrix spiking solution and a mixture of Aroclor 1016 and 1260.

  - The GPC calibration is acceptable if the recovery of pesticides in the matrix spiking solution is within 80 to 110 percent.

1.9.3 Evaluation

- o Florisil Cartridge Cleanup: Review Form 9A to verify that %Rs of the spiked pesticides are within 80-120 percent, and that the recovery of 2,4,5-trichlorophenol is < 5 percent.

- o GPC: Review Form 9B to verify that %Rs of pesticides in the matrix spiking solution are within 80-110 percent.

1.9.4 Action

- o If florisil cartridge check criteria are not met, use professional judgment to qualify data.

- o If zero recovery was obtained for the pesticide compounds and surrogates during either check, nondetected target compounds may be suspect and data may be qualified unusable (R).

- o If recoveries are > 120 percent for either check, positive results should be qualified as estimated (J) and nondetects require no qualification.

1.10 Target Compound Identification and Confirmation

1.10.1 Review Items

Form 1, Form 6D and 6F, and Form 10A and 10B.

1.10.2 Criteria

- o Second-column confirmation is required for all compounds detected on the primary column.

- o Compound identification must be within RT windows established by the daily calibration for <u>both</u> columns.

- o Both chromatographic columns will be required to have full calibration and be in control when analyses are performed.

- o The following guidance for reporting detected compounds confirmed by second-column confirmation is recommended:

  - When the confirmation column result is within ± 25 percent of the primary analysis, the primary column result shall be reported.

  - If the confirmation analysis is > 25 percent of the primary analysis, the lower of the two values shall be reported.

  - QC criteria (i.e., surrogate recoveries, MS/MSD recoveries, etc.) and holding time requirements must be considered when selecting which GC column result is to be reported.

1.10.3 Evaluation

- o For compounds detected and reported on Form 1, review Forms 10A and 10B to verify that sample RTs are within RT windows on both columns, and that confirmation on an alternate column was performed.

- o Evaluate the adherence to QC and holding time requirements for both GC column analyses for compound result reporting purposes.

1.10.4 Action

- o If sample compound RTs are not within RT windows specified on Forms 10A and 10B for both columns, the compound reported as detected should be considered nondetected.

- o If second-column confirmation was not performed for target compounds detected during the primary analysis, results should be qualified as unusable (R).

- Ensure that detected compound results have been reported according to guidance in Section 2.9.2.

DATA VALIDATION CRITERIA FOR MODIFIED METHOD 8015

1.0 Technical Holding Time

1.1 Review Items

Form 1, COC forms, case narrative, and laboratory sample receipt form.

1.2 Criteria

For Modified Method 8015 in cooled (4°C ± 2°C) water samples, the holding time is 7 days from time of sample collection to extraction, and 40 days from sample extraction to analysis.

For Modified Method 8015 in cooled (4°C ± 2°C) non aqueous samples, the holding time is 14 days from time of sample collection to extraction, and 40 days from sample extraction to analysis.

For Modified Method 8015 water and non aqueous Gasoline Range Organics (GRO) analysis, the holding time is 14 days from time of sample collection.

1.3 Evaluation

For sample extraction, compare the sample collection date on the COC form with the date of extraction on Form 1.

For sample analysis, compare the dates of extraction and analysis reported on the sample Form 1.

Verify that samples were received intact at a temperature of 4°C ± 2°C. This information should be located on the laboratory sample receipt form.

1.4 Action

If samples were not received and maintained at 4°C ± 2°C, use professional judgement to evaluate the possible effect on data.

If criteria for holding times are exceeded, qualify positive results as estimated (J), and nondetects as estimated (UJ).

If holding times for sample extraction or analysis are grossly exceeded (i.e., by a factor of two or more), qualify positive results as estimated (J), and nondetects as unusable (R).

Use professional judgement in qualifying results for detected compounds when primary column analysis is performed within holding time, but second-column confirmation analysis exceeds holding time requirements.

2.0 Initial Calibration

2.1 Review Items

Form 6F.

2.2 Criteria

A three- to five- point calibration of Modified Method 8015 target compound standards must be analyzed at the beginning of each analytical sequence, or as necessary when continuing calibration acceptance criteria are not met.

Standards must be analyzed on the GC column and instrument used for analysis.

One calibration standard should be at or near MDL, and standards should not exceed the working range of the GC system.

For external standard calibration: If the calibration factor RSD is constant over the working range (i.e., <10-20 percent RSD), the average calibration factor may be used for sample quantitation in place of a calibration curve.

Note: The acceptable percent RSD for calibration factors is specified by the analytical method performed.

For IS calibration: If the response factor RSD is constant over the working range (i.e. <10-20 percent RSD), the average response factor can be used for sample quantitation.

2.3 Evaluation

Verify that the correct number and concentration of standards were used for initial calibration, and that standards were analyzed on each column and instrument used for sample analysis.

If the external standard calibration method was used for sample quantitation, ensure that the calibration factor percent RSD listed on Form 6F meets method requirements.

If the IS calibration method was used for sample quantitation, ensure that the response factor percent RSD listed on Form 6F meets method requirements.

2.4 Action

If the number and concentrations of calibration standards required by the method were not analyzed, samples associated with that calibration curve must be carefully evaluated to determine the usability of data.

If the percent RSD linearity criteria are not met for compounds being quantified, qualify all associated positive quantitative results as estimated (J). When the percent RSD is grossly exceeded (i.e. > 50 percent), nondetects may be qualified as estimated (UJ).

3.0 Continuing Calibration

3.1 Review Items

Form 7 and Form 8.

3.2 Criteria

A continuing calibration standard must be analyzed every ten samples, at the beginning of the analysis, end of the shift or end of a set. to verify the calibration curve, calibration factors, or

response factors. If the response for any analyte varies by more than ± 15% a new calibration curve must be prepared for that compound

The %D between the continuing calibration standard response for any parameter and the predicted response must be within ± 15%..

3.3 Evaluation

Check Form 8 to verify that continuing calibration standards were analyzed daily and at the proper frequency and concentration.

Verify that RTs for target compounds in the continuing calibration standard are within RT windows established by the initial calibration listed on Form 6.

Verify that the continuing calibration standard %D from the initial calibration is within the method-specified limits.

If the continuing calibration standard was not analyzed as required, professional judgement must be used to determine if data should be qualified.

If continuing calibration standards do not fall within RT windows, associated sample results should be carefully evaluated. All samples injected after the last in-control standard are potentially affected.

If the %D exceeds criteria for the compound(s) being quantified, qualify all associated positive results as estimated (J). Nondetects should be qualified as estimated (UJ) when the difference exceeds 50 percent.

4.0 Laboratory Blanks

4.1 Review Items

Form 1 and Form 4.

4.2 Criteria

No contaminants should be present in laboratory blanks.

A method blank must be analyzed for each 20 samples of similar matrix in each SDG or whenever a sample extraction procedure is performed. A method blank must be analyzed on each GC column and instrument used to analyze the reported sample group.

4.3 Evaluation

Review the results of all associated laboratory blanks, Form 1 and Form 4, to evaluate the presence of potential target range compounds.

Verify that a method blank analysis has been reported per SDG, per matrix, per concentration level and extraction batch, for each GC system used to analyze samples.

4.4 Action

If a target range compound is found in a laboratory blank but not in the sample(s), no qualification is required.

The sum of all target range compounds detected in the sample and also detected in an associated laboratory blank is qualified if the sample concentration is <5X the blank concentration:

If the sample concentration is ≥ the EQL or reporting limit, the result is considered a nondetect and qualified (U).

If the sample concentration is < the EQL or reporting limit, report the result at the EQL or reporting limit with a μ qualifier.

If the sample result is >5X the blank result and greater than the CRQL or reporting limit, the sample result is not qualified.

5.0 Equipment Rinseates, Trip Blanks, ANS ASTM Type II Source Water Check Samples

5.1 Review Items

Results for equipment rinseates, trip blanks, and ASTM Type II source water check samples associated with the collection and shipping of environmental samples and decontamination of sampling equipment.

5.2 Criteria

Ideally, no target analysis should be present in equipment rinseates, trip blanks, ASTM Type II source water check samples.

5.3 Evaluation

Review associated equipment rinseate, trip blanks, and ASTM Type II source water results (Form 1s) to determine if contamination has resulted because of sample collection shipment and equipment decontamination procedures.

5.4 Action

Use professional judgement when qualifying sample results based on equipment rinseate, tip blanks, and ASTM Type II source water results. All equipment rinseate and ASTM Type II source water check samples collected during the sampling event or field effort may need to be reviewed to determine if trends in contamination are occurring.

6.0 Matrix Spikes/Matrix Spike Duplicates

6.1 Review Items

Form 3, QC check sample results (if required).

6.2 Criteria

MS/MSD samples are analyzed at a frequency of a least 1 MS and MSD per 20 samples of similar matrix.

MS recoveries should be within control limits provided on Form 3.

RPD between MS and MSD recoveries should be within control limits provided on Form 3.

If required by the method, a QC check sample must be analyzed for compounds that do not meet the MS/MSD %Rs listed on Form 3.

6.3 Evaluation

Verify that MS and MSD samples were analyzed at the required frequency and that results are provided for each sample matrix.

Inspect MS/MSD results reported on Form 3 and verify that the results for recovery and RPD are within control limits.

If required by the method, ensure that a QC check sample was analyzed for MS compounds not meeting acceptance criteria.

6.4 Action

No action is taken on MS/MSD data alone. However, using the MS/MSD results in conjunction with other QC criteria, including QC check sample results, some qualification of the data may be required.

7.0 Target Compound Identification and Confirmation

7.1 Review Items

Form 6 and Form 10

7.2 Criteria

Compound identification must be within RT windows established by the daily calibration of the column.

The chromatographic column will be required to have full calibration and be in control when analyses are performed.

7.3 Evaluation

For compounds detected and reported on Form 1, review Form 10 to verify that sample RTs are within RT windows on both columns, and that confirmation on an alternate column was performed.

Evaluate the adherence to QC and holding time requirements for both GC column analyses for compound result reporting purposes.

7.4 Action

If sample compound RTs are not within RT windows specified on Form 10, the compound reported as detected should be considered nondetected.

THIS PAGE INTENTIONALLY LEFT BLANK

STANDARD OPERATING PROCEDURE NO. 1
MAGNETIC GEOPHYSICAL TECHNIQUES

1.0 OBJECTIVE

The objective of this procedure is to delineate specific procedures for conducting surface geophysical surveys, including total field and gradient surveys, using magnetic techniques. These techniques may be used to

- locate buried ferrous debris (e.g., 55-gal drums, ordnance, scrap metal);
- define boundaries of trenches or landfills containing ferrous material;
- locate ferrous underground utilities (e.g., pipes and tanks);
- select intrusive sites that are clear of buried metal obstructions;
- locate permeable pathways associated with nonorganic contaminants; and
- map regional geologic structure.

2.0 BACKGROUND

Magnetic surveys are used to measure the earth's magnetic field and variations of the field. For environmental applications, such a survey is used principally to detect ferrous metal in the subsurface. Magnetometers can detect small, localized variations in the earth's magnetic field. Magnetic surveys typically are performed using a fluxgate, proton precessional, or optically pumped (cesium vapor-type) magnetometer. Although there are differences in resolution between each of these instruments, the most common type of magnetometer used for environmental or engineering surveying is the proton precessional magnetometer. Therefore, this SOP will restrict discussions to this type of magnetometer for basic operational information because survey design will not change as a result of equipment differences.

The proton precessional magnetometer is mounted on a staff and has a sensing chamber that is filled with a proton-rich fluid (Decane). When a small, alternating current is passed through a current coil within the chamber, a small magnetic field is produced. Protons within the fluid align themselves with this temporary magnetic field. When the current is turned off, the magnetic field ends and the protons attempt to realign (precess) about the earth's magnetic field. A small signal is generated by the precessing protons in the same coil used to polarize them. The signal

measured is directly proportional to the total magnetic field intensity at that location. This intensity is displayed digitally on the magnetometer and expressed in nanotesla or the equivalent magnetic term of gammas. The unit of magnetic measurement is the nanotesla, but historically was defined as the gamma. Therefore, most magnetometers in use today and existing field data and literature are expressed in gammas.

$$1\ GAMMA = 1\ NANOTESLA\ (NT) = 10^{-9}\ TESLA = 10^{-5}\ GAUSS$$

Magnetic gradiometry (gradient surveys) uses the same instrumentation as routine magnetic surveys and includes two total field magnetometer sensors mounted vertically on a staff with a typical separation of either 1.5 or 3 ft between the two sensors. The acquisition system collects data from both sensors simultaneously (or nearly so); the difference between the two intensities is the vertical magnetic gradient. The response of the gradiometer varies by one over the distance to the target to the fourth power ($1/d^4$) compared to one over the distance cubed ($1/d^3$) for the total field magnetometer (Benson et al., 1983). This fundamental difference results in the total field magnetometer's being more sensitive but also more susceptible to noise. Conversely, the gradiometer is less sensitive to the magnetic field. However, it is also less sensitive to background magnetic noise, which allows for better definition of near-surface anomalies; and it automatically corrects for regional gradient and time variations of the Earth's magnetic field. (please review last two sentences and compare with original to ensure I did not change the meaning) These corrections will be discussed later in the text. Because of the nature of most geophysical targets within the environmental field, HAZWRAP recommends using a magnetic gradiometer for the mobile field magnetometer in most surveys.

Magnetic values (or magnetic gradient values) are plotted on a map so their variation over the site can be analyzed. Buried subsurface metal can be indicated by anomalously high values or changing values. Magnetic response is proportional to the mass of the subsurface magnetic material. Typically, a single 55-gal drum can be detected to a depth of 20 ft. Large concentrations of drums can be detected at depths of 30 to 40 ft or more.

3.0 RESPONSIBILITIES

Site Manager: The Site Manager, or Field Team Leader, is responsible for ensuring that field activities are completed to meet the project objectives, are conducted in accordance with the project plans and requirements, and that all activities are performed according to the respective procedures. The Site Manager is responsible for ensuring that all site personnel are trained in the procedures, that the procedures are adhered to, and that all activities are documented.

Field Team: All members of the field team (samplers, technicians, field geologists, engineers, etc.) are responsible for understanding and implementing this field procedure as well as ensuring that all of the team members also perform in accordance with this procedure.

It is the responsibility of all field personnel to identify, document, and submit recommendations to improve the quality, usability, and implementability of this procedure.

4.0 REQUIRED EQUIPMENT

The following equipment is necessary to properly complete a magnetic survey:

- two magnetometers [one field (mobile) and one base station recording magnetometer];
- field notebook (waterproof, bound type);
- indelible, waterproof pen;
- site map;
- nonferrous tape measure [minimum of one 15-m (50-ft) tape, but four 100-m (300-ft) tapes simplify survey layout];
- measuring wheel (1-ft increment minimum, nonconductive). (This equipment is optional if four nonferrous tape measures are used for the survey.);
- wooden stakes, plastic surveyor's flags, or PVC pipe to mark survey corners (must be nonferrous material if present during survey);
- surveyor's flagging;
- black electrical tape (for unexpected repairs); and
- personal computer
  - IBM PC, PC/AT, PC/XT, and compatibles;

- minimum 640K available memory;
- DOS 2.1 or higher;
- floppy drive (5.25-in. or 3.5-in.);
- VGA, EGA, or CGA graphics capability; and
- serial port (RS-232); and

- software to
  - download data stored in the magnetometers memory,
  - generate ASCII data files for submission to HAZWRAP,
  - perform diurnal corrections on the data,
  - produce profile plots,
  - produce contour diagrams, and
  - produce final interpretive diagrams.

5.0 PROCEDURES

5.1 SETUP

Setup consists of preparing the site and personnel for the survey to be performed. The setup procedure ensures that certain minimum preparations have been made before initiation of any data collection. Proper initiation procedures include

- informing the field personnel of all known hazards that may pose a potential threat to their safety; (this information will be conveyed and understood by all members of the survey team, particularly the Site Manager and Health and Safety Officer, who have direct responsibility for the survey teams safety);
- clearly defining the purpose and expectations of the subsurface investigation;
- reviewing all existing site conditions data available that may impact the data quality objectives of the survey; and
- defining general field parameters appropriate for the purpose of the survey (total magnetic field vs magnetic gradient measurements).

Defining general field parameters must also consider the following:

- Spacing between stations controls the lateral degree of resolution available (i.e., size of the anomaly that can be resolved); a spacing of 5 to 100 ft is commonly used. Actual station spacing chosen must weigh resolution desired. The spacing must be less than the lateral variation of the anomaly that is expected;
- Definition of a magnetic anomaly requires several (three or more) anomalous readings; and
- Background magnetic noise must be evaluated and/or determined to assess the potential usefulness of a magnetic survey. High noise levels can make interpretation difficult and can cause significant anomalies to be overlooked. Actual background noise must be considered during data collection and interpretation.

The survey grid can now be established according to specification listed in SOP 3A. Note all line locations, azimuths, and lengths of the original survey lines in the field notebook.

5.2 CALIBRATION

Calibration of the magnetometer is generally completed by the manufacturer and will not be required in the field. However, because of the nature of the earth's magnetic field, variations in intensity may occur over time. Variations that occur during the course of the day are known as diurnal variations and may exhibit intensity changes of 100 gammas or more. Superimposed on the diurnal variations are less-intense, shorter-period variations known as micropulsations. Micropulsations may cause changes of a thousandth of a gammas to tens of gammas and are generally more random in behavior than diurnal variations.

Because of these natural variations in the magnetic field, it is necessary to collect data that will be used to "correct" the survey data. This is step completed by placing a base station magnetometer at a location that is relatively free from magnetic interference (cars, people, fences, buildings, etc.) to collect magnetic data at short time intervals. The base station magnetometer should be placed a sufficient distance away from objects that can cause magnetic field disturbances and no further than 50 miles from the survey location. Table 1 lists estimated anomaly intensities with respect to distance for several commonly encountered objects. The maximum time between acquisition of base station data should be 5 min but is commonly less. To determine the acquisition time interval between automated base station recordings, estimate the time between

successive data collected from the mobile field magnetometer. A base station reading should be collected before and after each individual field magnetic reading. Therefore, if data are acquired with the mobile magnetometer at an average of every 20 sec, the base station should be collecting data every 10 sec. This will minimize interpolation errors when performing postsurvey diurnal corrections. Available memory on the base station magnetometer and equipment limitations (most proton precessional magnetometers can only collect a data point every 3 or 4 sec) must also be considered when determining the proper acquisition time interval. The base station data are then used during reduction of the day's survey data to filter out the natural magnetic variations from those caused by variations in subsurface or surface conditions along the survey grid. Additionally, if the survey is expected to encompass more than 1 day, comparisons between data collected on different days can be made to determine whether major magnetic storms occurred during the survey. This information can be used to determine whether data precision is acceptable because it may be impossible to collect high-resolution magnetic data during large magnetic storms.

Table 1. Anomaly intensities of common objects (modified after S. Breiner 1973)

Object description	Near distance (m)	Magnetic intensity (Nt)	Far distance (m)	Magnetic intensity (Nt)
Automobile (1 ton)	10	40	30	1
Ship (1000 tons)	30	300 to 700	300	0.3 to 0.7
Light aircraft	7	10 to 30	15	0.5 to 2
Steel file (25 cm long)	1.5	50 to 100	3	5 to 10
Screwdriver (12 cm long)	1.5	5 to 10	3	0.5 to 1
Revolver (.38 or .45 automatic, assuming that the induced magnetization is approximately equal to the permanent magnetization)	1.5	3 to 7	3	1 to 2
Rifle	1.5	10 to 50	3	2 to 10
Ball bearing (2 mm)	0.08	4	0.16	0.5
Cyclone fence	3	20	7.5	1 to 2
Steel pipeline (30 cm diameter)	7.5	50 to 200	15	12 to 50
DC train	150	5 to 200	300	1 to 50
Steel well casing and wellhead	15	200 to 500	150	2 to 5
55-gal steel drum (~18 kg/40 lb)	1.5	80	3	12

5.3 DATA COLLECTION

A standard field procedure for collecting magnetic survey data is described below.

- The instrument battery will be checked for sufficient charge and the instrument tested using manufacturer's procedures for proper operation;

- Set up the base station magnetometer according to the manufacturer's instructions. The base station should be at a location that is free from magnetic interference and should be at the same location each day if surveys are conducted over more than 1 day;

- Check the tuning of the instrument to ensure that the magnetic field reading agrees with the nominal value of the magnetic field shown for the region. More-accurate values for each survey region are available from current magnetic intensity maps or commercially available computer programs;

- Synchronize the base station and mobile field magnetometer's date and time functions to allow for postsurvey data corrections for diurnal fluctuations and micropulsations. Data for the mobile field magnetometer should be simultaneously collected with the base station magnetometer at the base station location at the beginning and end of each day. This simple quality control check helps determine daily equipment operation and consistency and, in the event of an equipment failure during the survey, allows the geophysicist to determine what survey data collected are still acceptable and which data should be discarded. This step assists in identifying equipment problems early, and only a maximum of 1 day of surveying may need to be repeated in case of an equipment failure;

- A visual survey along the proposed lines will be conducted. The visual survey will include a review of site utility plans and notations of overhead wires, manhole covers, buried cables, or indications of buried pipe lines. Site locators will assist in confirming the presence of any possible telephone and utility features;

- Excessive amounts or large pieces of metal on the ground surface will be noted in the field notebook;
- During each reading, the arrow on the magnetometer sensing chamber should be oriented towards magnetic north, and the sensor staff must remain vertical during measurements; and
- Take a reading at each survey location. Additional readings are required in the following cases:
  - no signal or a weak signal is generated by the sensor, or
  - abnormally high gradient or noisy conditions are indicated by the magnetometer.

The reading used for this location will be an average value of the consecutive readings collected at this location.

- Record readings, time of the readings, and station location in a field notebook or data logger;
- The above procedure will be continued for each station along the line;
- Data will be downloaded from the data logger or field notebook to the computer for analysis;

6.0 DATA REDUCTION AND INTERPRETATION

The standard procedure for reducing and interpreting magnetic data follows.

- Magnetic values must be corrected for magnetic drift and corrected values plotted at each station location, thus producing a series of profiles or a grid plot. Data should also be contoured to determine what variations of the magnetic field exist; and
- Using available information (borehole, geophysical, site conditions), interpret the magnetic anomalies with respect to possible sources.

7.0 RESTRICTIONS/LIMITATIONS

As with all geophysical techniques, the effectiveness of magnetic surveys is greatly affected by the data interpretation and technique applicability. Geophysical data should always be interpreted by an experienced geophysicist with the assistance of the best available site information. For

example, if a magnetic survey is to be conducted to locate a drum burial site, site information regarding reputed burial locations and other potential targets that may interfere with burial site location should be reviewed before conducting a survey and during data collection and interpretation. Additional limitations that may affect the usefulness of magnetic surveys are the existence of magnetic storms. Magnetic storms are large (several hundred gammas) variations in the earth's magnetic field that may occur suddenly several times a month and are generally related to high levels of solar activity (i.e., sunspots, etc.). The high intensity of magnetic storms makes high-resolution magnetic measurements nearly impossible, even with base station corrections. It is recommended to monitor WWV 5, 10, 15, 25 MH for solar flux rates before beginning field activities. Finally, magnetic surveys cannot always be successfully conducted in congested areas that contain large magnetic sources (i.e., power lines, railroad switchyards, communication lines, etc.).

STANDARD OPERATING PROCEDURE NO. 2
EM-34 TERRAIN CONDUCTIVITY METER

1.0 OBJECTIVE

The objective of this procedure is to delineate specific procedures for collecting electromagnetic (EM) data using the Geonics EM-34 Terrain Conductivity Meter. Additionally, this document will provide guidance for the proper use of this technique (including proper application, survey design, pitfalls, and data interpretation).

2.0 BACKGROUND

The EM-34 is an EM tool that can be used to perform terrain conductivity surveys via inductive measurement. EM surveys can be used as a nondestructive, noninvasive, and potentially cost-effective method to aid in characterizing and assessing potentially contaminated sites.

EM surveys measure the electrical conductivity of the subsurface soil, rock, and groundwater. Conductivities measured by the EM-34 generally are a function of the physical properties of the soil and rock such as magnetic susceptibility, porosity, and permeability. Terrain conductivity measurements can also vary as a function of the physical properties of pore fluids (groundwater) contained in the subsurface materials. Varying conductivities can be attributed to:

- soil moisture content;
- stratigraphy;
- fractures;
- voids;
- pore fluid composition;
- localized organic content, clay, sand gravel, or salt-rich zones (mineralogy); and
- EM anomalies (e.g., power lines and electric fences).

The EM-34 can be operated in both horizontal and vertical dipole modes and at three coil spacings, thus giving the user the ability to perform profiling using six instrument configurations. This aspect permits the user to collect EM data from six different depths with the EM-34, and essentially results in a separate sounding at each data collection point on a survey line. It is

important to note, however, that data collected from the deeper effective depths are a result of the combined conductivities of the preceding (upper) layers. This generally results in a smearing of the true conductivity variation with depth unless proper data reduction techniques are used.

Although the EM-34 can be used in six instrument configurations, the operation of the instrument does not vary with the configuration. Additionally, profiling and sounding operations are identical except that soundings are simply profiles conducted at one location. As a result, the procedures and equipment described in the following sections can be used for all EM-34 configurations and applications.

3.0 RESPONSIBILITIES

Site Manager: The Site Manager, or Field Team Leader, is responsible for ensuring that field activities are completed to meet the project objectives, are conducted in accordance with the project plans and requirements, and that all activities are performed according to the respective procedures. The Site Manager is responsible for ensuring that all site personnel are trained in the procedures, that the procedures are adhered to, and that all activities are documented.

Field Team: All members of the field team (samplers, technicians, field geologists, engineers, etc.) are responsible for understanding and implementing this field procedure as well as ensuring that all of the team members also perform in accordance with this procedure.

It is the responsibility of all field personnel to identify, document, and submit recommendations to improve the quality, usability, and implementability of this procedure.

4.0 REQUIRED EQUIPMENT

The following is a list of equipment necessary for the proper completion of an EM survey using the EM-34:

- Geonics EM-34 Terrain Conductivity Meter and associated cables;
- field notebook (waterproof, bound type);
- indelible ink pen;
- site map;

- engineer's tape measure (50-ft minimum);
- measuring wheel (1-ft increment minimum);
- stakes or surveyor's flags;
- surveyor's flagging; and
- black electrical tape.

5.0 PROCEDURES

5.1 SETUP

Setup consists of preparing the site for the survey to be performed. The setup includes layout of the survey locations on the ground so the survey can be repeated both with different coil spacings and during subsequent surveys (later dates or additional geophysical techniques). This does not necessarily require professional surveying; however, should the ends of profile lines or the locations of EM soundings be surveyed so that the work performed can be repeated at a later date. The setup should proceed as follows:

- Mark the survey lines with stakes and flagging at sufficient intervals. Indicate the line designation (number or letter) and location on each stake; and
- Using the measuring wheel and surveyors flags, mark the reading locations (at the desired spacing) between the line endpoints. The field technician should assist to ensure a straight survey line.

Note all line locations, azimuths, and lengths in the field notebook.

5.2 CALIBRATION

The EM-34 is calibrated by the manufacturer (Geonics); however, on large-scale projects and when the potential for resurveying an area with a different instrument or at a later date is high, a local standard site in the field must be chosen to provide a reference base station. This will allow the user to check for instrument drift or variations between instruments. To complete the calibration reading, perform the following steps:

1. Select a site away from surface or subsurface interference and obtain a reading with the EM-34 in the various instrument configurations that will be used or have been used in the past for surveys. Obtain readings at the start and end of each day;
2. In the field notebook, record the time, site location, orientation of the instrument (i.e., azimuth of long axis of instrument configuration), instrument configuration (coil spacing, coil orientation), and the EM reading; and
3. During subsequent surveys, obtain calibration readings at the same locations and at the same frequencies as those in the original survey.

The calibration readings can be used to note and correct for variations in the instrument or variations between instruments.

5.3 DATA COLLECTION

Data collection for EM profiles consists of traversing the survey lines and recording conductivity readings at designated intervals and at various coil spacings. Data collection for EM soundings consists of recording conductivity values at a single location at various coil spacings. For both sounding and profiling, the data recording procedure is the same except profile data are recorded at various locations and sounding data at one location.

1. Set up the EM-34 according to the manufacturer's instructions. Begin profiling and sounding with the shortest coil spacing;
2. Mark the center of the connecting cable with surveyor's flagging so that it is clearly visible;
3. With the center of the connector cable at the first reading location, record the conductivity reading and location in the field notebook;
4. If sounding, repeat steps 1–3 with the next coil spacing;
5. If profiling, proceed to the next location on the survey line and, with the center of the connector cable at the location, record the conductivity reading and location. Repeat until data at all locations on the survey line have been recorded;
6. Repeat steps 3 and 4 for all survey lines in close proximity to each other; and
7. When finished, repeat all steps with the next coil spacing.

The above process may be repeated six times in the following EM-34 system configurations:

Horizontal dipole (vertical coils) mode:
- 10-ft coil spacing
- 20-ft coil spacing
- 40-ft coil spacing

Vertical dipole (horizontal coils) mode:
- 10-ft coil spacing
- 20-ft coil spacing
- 40-ft coil spacing

The number of configurations used to collect site data will vary depending on the goals of the survey. Please refer to the technical guidance for EM techniques at the beginning of this section for guidelines regarding survey design.

6.0 RESTRICTIONS/LIMITATIONS

As with all geophysical techniques, the effectiveness of EM surveys using the EM-34 are greatly affected by the data interpretation and technique applicability. Geophysical data should always be interpreted by an experienced geophysicist with the assistance of a qualified scientist from the field of study in which the data are to be applied. For example, if the data are to be used to evaluate geologic and hydrogeologic conditions beneath a site, the data should be interpreted with the assistance of both a hydrogeologist and a geologist so that any interpretation provides realistic and necessary information.

THIS PAGE INTENTIONALLY LEFT BLANK

STANDARD OPERATION PROCEDURE NO. 3
GROUND-PENETRATING RADAR SURVEY

1.0 OBJECTIVE

The objective of this procedure is to delineate specific procedures for use of ground-penetrating radar (GPR) surveys. Additionally, this document will provide guidance for the proper use of this technique (including proper application, survey design, pitfalls, and data interpretation).

2.0 BACKGROUND

GPR systems are similar to electromagnetic (EM) systems in that a source and a receiver are needed. A radar antenna (source) emits an EM pulse several times a second. These EM impulses are then directed into the ground in the form of waves. As the waves penetrate deeper through the geologic material, contrasts in electrical properties are encountered with changes in strata. These electrical contrasts (anomalies) cause some of the wave to be reflected back toward the surface, where it is received by an antenna, while some of the wave continues downward. The time interval between the point when the EM signal is emitted to the time it is reflected and received is dependent on the properties of the material and on the depth at which the signal is reflected.

The contrasts in electrical properties are a function of the composition of the materials and moisture contents. Generally, good conductors, such as metal drums, reflect the entire radar signal (EM wave), so there is no penetration below this point. Poor conductors, such as unsaturated sands, will generally allow for a deeper radar signal penetration than good conductors such as saturated clays or saline water. Typical GPR antennae range in frequency from 10 megahertz (MHz) to 1000 MHz, with 300 to 600 MHz being considered as standard. The lower the frequency, the larger the antenna, so some lower-frequency antennae are commonly towed by vehicles, while the higher-frequency ones can be towed by an individual. Although lower-frequency antennae permit deeper penetration, they lack the resolution of the higher-frequency antennae. Typical penetration in stratified saturated sands for the 300-MHz antenna is about 50 ft and for the 600-MHz antenna about 25 ft.

GPR equipment does not sense only straight below the antenna; instead, it senses forward, backward, and to the sides at various angles. For this reason, some objects can be detected without having the equipment pass directly overhead.

3.0 RESPONSIBILITIES

Site Manager: The Site Manager, or Field Team Leader, is responsible for ensuring that field activities are completed to meet the project objectives, are conducted in accordance with the project plans and requirements, and that all activities are performed according to the respective procedures. The Site Manager is responsible for ensuring that all site personnel are trained in the procedures, that the procedures are adhered to, and that all activities are documented.

Field Team: All members of the field team (samplers, technicians, field geologists, engineers, etc.) are responsible for understanding and implementing this field procedure as well as ensuring that all of the team members also perform in accordance with this procedure.

It is the responsibility of all field personnel to identify, document, and submit recommendations to improve the quality, usability, and implementability of this procedure.

4.0 REQUIRED EQUIPMENT

The following is a list of equipment necessary for the proper completion of a EM survey using GPR.

- GPR system;
- field notebook (waterproof, bound type);
- indelible ink pen;
- site map;
- engineer's tape measure (50-ft minimum);
- measuring wheel (1-ft increment minimum);
- stakes or surveyor's flags;
- surveyors flagging; and
- black electrical tape (for unexpected repairs).

The standard array of GPR instrumentation consists of a transmitter/antenna unit(s), a DC power supply, a control unit, the signal-processing circuitry connected to the antenna by a cable, an oscillograph or video display unit, and a plotter or an analog or digital recording device. The field equipment may be vehicle mounted, but it is small enough to be hand carried into areas not having vehicle access. Examples of GPR units are Geophysical Survey Systems, Inc.'s (GSSI) SIR System 8 and System 10 systems. Both GSSI systems use impulse radar technology to sense and record continuous, high-resolution profiles of subsurface materials.

The primary variable in GPR instruments is the antenna configuration. Antennas currently are available in both monostatic (one-piece) and bistatic (two-piece) configurations and are generally designed to detect radar signals ranging from 60 to 1000 MHz.

5.0 FIELD PROCEDURES

5.1 PLANNING

The planning phase of a GPR survey requires the development of information pertaining to the geophysical characteristics of the site and how these characteristics might vary across the area to be surveyed. The type and structure of soils and geologic formations are critical factors that should be known. In addition to developing information about the characteristics of earth materials present at the site, the Project/Field Geophysicist needs to develop information about the targets of interest and factors that may interfere with execution of the survey or cause excessive noise in the acquired data. If possible, it is useful to know the depth, size, shape, and type of potential targets to be detected. The depth and size of the objects are very important factors that permit the appropriate antenna configuration and spacing between survey lines to be selected. Surveys over known objects on site are useful to cross-check calculations; however, they are not absolutely necessary. Other specifications include accuracy of locational resolution desired, probable weather conditions during site activities, and the type and sophistication required for data interpretation and presentation.

The important instrument selection decision for the survey lies in the determination of the optimal antenna. Generally, the higher the antenna frequency, the smaller the object that it can resolve and the smaller its depth of penetration. The optimal antenna is the one with the highest resolution that will have sufficient depth of exploration. However, the depth of penetration for a given

antenna will vary widely between sites, primarily because of soil moisture content and the clay/sand ratio of the soils. Overnight rainfall can often elevate the soil moisture content such that an antenna's depth of penetration can be degraded by 30% in a few hours. No one antenna configuration is suitable for all cases, even at the same site. Ideally, the survey crew should carry multiple antennas to the site for the survey so that an optimal configuration is always available.

The survey grid should be designed such that the GPR measurements are spaced to adequately define the distribution and extent of the exploration targets. For convenience, an orthogonal survey grid, located relative to a known location, is usually established over the survey area and the GPR measurements and anomalies are located by their grid coordinates (x,y). This is a convenient method for recording the data in an organized manner, for graphically displaying the data, and for ease of locating the anomalies detected. For determination of geologic features or to detect large targets, reconnaissance-type, low-resolution surveys are typically performed with a track spacing of 5 to 15 ft. Surveys to detect small discrete targets or to resolve target details require a track spacing of 2 to 5 ft.

5.2 SITE LAYOUT

Setup consists of preparing the site for the survey to be performed. This includes layout of the survey locations on the ground so that the survey can be repeated both with different coil spacings and during subsequent surveys (later dates or additional geophysical techniques). This does not necessarily require professional surveying; however, the ends of profile lines should be referenced to known features so that the work can be repeated at a later date.

Clearly mark the survey lines with stakes and flagging at sufficient intervals so that the line can be easily followed (survey preferable). Clearly indicate the line designation (number or letter) and location on each stake. Using the measuring wheel and surveyors flags, mark the reading locations (at the desired spacing) between the line endpoints. The Field Technician should spot the line to maintain a straight survey line. Note all line locations, azimuths, and lengths in the field notebook. Traverse spacing should be designed so that the target of interest will not be "missed" by the survey.

GPR surveys are performed by establishing a grid of parallel survey lines across the site and moving the radar antenna along each of these lines. Spacing between the lines is dependent on

the size and depth of the targets of interest and the objectives of the survey (i.e., reconnaissance or detailed survey). GSSI systems employ an electronic marking device that records a mark on direct field graphic records or within digital radar files. Generally, double marks or clicks are made at the beginning and end of the survey lines and single clicks are recorded as the antenna passes over predetermined distance intervals. Following acquisition of data in the field, the data are downloaded from digital tape to magneto-optical storage media for subsequent processing and analysis in the office. This provides an efficient means of accessing the data, as well as redundant storage.

5.3 DEPTH DETERMINATION

To determine the depth of anomalies noted on radar profiles, convert the travel-time data actually recorded to depths by determining the transmission velocity(ies) associated with the earth's materials. The velocity of electromagnetic waves within the subsurface at the site may be determined through excavation of observed targets to determine their depth of burial. Several excavations may be made and an average or range of transmission velocities for materials at a given site may be determined. After velocity values are determined, interpretations or determinations concerning the depths of other signatures or anomalies may be made. Two other simpler methods, discussed in the following section, provide a simple means of determining the radar-wave velocities through subsurface materials and, therefore, a means for converting travel times to depths. These are two graphical approaches, one involving examination of hyperbolic signatures and the other involving the examination of changes in the travel time within a given subsurface section as the transmitter and receiver antenna (bistatic configuration) are moved away from each other. The latter is referred to as wide-angle radar reflection measurements.

5.4 GROUND-PENETRATING RADAR SURVEY MEASUREMENTS

After an optimal GPR survey configuration has been determined, the survey itself is straightforward (barring changes in the subsurface electrical characteristics). The unit is activated and the antenna is towed along one of the prearranged grid lines. An electronic mark is placed on the data at the beginning and end of each survey line and at every 10- or 20-ft interval along the line so that the position of the data and anomalies on each radar line are readily apparent. The locations of surface metal, utilities, walkways, etc., are noted in the logbook during the survey.

5.5 QUALITY CONTROL AND CALIBRATION

5.5.1 Quality Control

Quality control (QC) procedures for GPR surveys require that trained geophysicists be used in all aspects of the survey including the preparation of the project work plans and survey designs, conduct of the survey, interpretation of the data, and presentation of the results. Work plans should be written such that some degree of latitude is given to the survey team so that they may adjust to site conditions. The objectives of the survey in terms of the (1) degree of detail needed and the size of the area to be surveyed; (2) type, depth, size, and composition of targets of interest (if known); (3) resolution required; (4) schedule limitations; (5) degree of sophistication required for data presentation and interpretation; and (6) specific deliverables required should be clearly defined.

5.5.2 Calibration

For reconnaissance surveys or for surveys where lateral resolution is more important than depth, the traces may be roughly calibrated by estimating the velocity of electromagnetic waves in the media at the site using published values for similar materials. The crudeness of the calibration is evidenced by considering that the velocity may vary by more than an order of magnitude, depending on the soil/rock properties and the moisture content.

For surveys requiring reasonable resolution of target depth, the travel time to targets of known depths must be determined at each site. As the radar trace is made over the known targets, the reflection patterns provide direct depth-calibration points on the trace. Sites with uniform lithology may require only a few depth calibrations, but generally it is necessary to perform these calibrations at several locations and at several depths throughout the area of interest. Each radar trace should be referenced to the calibration most representative of the trace coordinates at the site. The preferred method is to use buried objects of known depth as calibration targets, or to excavate to detected objects and measure their depth below ground surface. A less desirable (but often necessary) procedure is to bury standard targets at various depths within the area of interest.

6.0 DATA FORMAT, PROCESSING, AND INTERPRETATION

6.1 DATA FORMAT

Although much of the data obtained in GPR surveys are automatically recorded by the instrumentation, additional information to unambiguously identify and to interpret each trace should be recorded in the field logbook. At a minimum, the field logbook should contain the following information:

- project name, number and location;
- company or organization;
- date and time of day;
- operator's name;
- line and trace designation (also recorded directly on the signal recording medium);
- equipment serial numbers;
- antenna frequency;
- direction and speed of antenna movement;
- weather and temperature;
- site map coordinates at the beginning and end of the trace;
- other pertinent notes, remarks or comments; and
- electromagnetic velocity in the subsurface medium at the nearest calibration point.

6.2 DATA PROCESSING

Reflected radar signals are electronically processed and displayed as an intensity-modulated time spectrum, where the time corresponds to target depth as described above. The series of signals corresponding to the reflected pulses as the antenna moves along a path forms a three-dimensional data set containing traverse distance, depth, and intensity information.

Typically, data are recorded on magnetic tape and/or displayed on a graphic recorder, with distance displayed along the *x*-axis, time (i.e., depth) displayed along the *y*-axis, and intensity given by the degree of darkness of the trace. In a typical survey, a series of parallel traverses are made with the GPR, and the series of graphical traces provide X-Y-Z locational and intensity of reflection information for targets of interest. Interpretation of anomalies in GPR traces requires

considerable subjective evaluation by a trained geophysicist. Extensive experience is required to distinguish target reflections from inherent system noise and interferences. In many cases, the anomalies caused by the targets of interest are small compared to varying reflections from the antenna system, the ground surface, geologic perturbations, and other interferences. Similarly, an acceptable interpretation of target depth from travel-time data requires knowledge of the varying geophysical characteristics across the site area surveyed.

A radar antenna transmits a "cone," rather than a thin beam of electromagnetic energy, that results in reflections obtained from objects not directly below the antenna. As the antenna moves across the plane of an object, reflections are obtained for a considerable distance along the antenna path. The radar reflections will generate a hyperbolic signature pattern. The size and shape of this hyperbolic signature varies as a function of the wave velocity within the subsurface materials, the size and orientation of the object relative to the radar wave pulse, and the rate, t, at which the antenna configuration is moved along the surveyed line. The signal travel times will vary corresponding to the distance between the antenna and the object.

A discrete spherical target, therefore, will generate a hyperbolic reflection pattern with the apex of the hyperbola corresponding to the location and depth of the object. Multiple or odd-shaped targets or targets of considerable size in comparison to the radar wavelength will generate complex reflection patterns consisting of overlapping hyperbolas. Thus, a true "picture" of subsurface objects is not obtained, and experience is necessary to translate the complex tracings into information concerning target depths, size, or shape.

7.0 RESTRICTIONS AND LIMITATIONS

The GPR has a number of limitations to its use. These are:

- limited depth of penetration, particularly in clay-rich soils;
- antenna ringing and other spurious electromagnetic noise that mask targets;
- limited three-dimensional data display capabilities; and
- limited target identification capabilities.

4.0 REQUIRED EQUIPMENT

4.1 DEFINITION AND EQUIPMENT

Sampling equipment includes split spoons, liners, hand augers, bailers, bowls, knives, scoops, water samplers, nondisposable filtration equipment, or any equipment that directly contacts samples. Equipment necessary to complete decontamination procedures includes:

- 5-gal or larger plastic buckets and/or troughs;
- laboratory-grade detergent (phosphate free);
- stiff-bristle brushes capable of cleaning the inside and outside of equipment;
- Teflon sprayers or wash bottles, or 2- to 5-gal manual pump sprayer (pump sprayer material must be compatible with the solution used);
- plastic sheeting;
- disposable wipes;
- aluminum foil;
- potable water;
- deionized, organic-free water [American Society for Testing and Materials (ASTM) Type II or equivalent] [high-pressure liquid chromatography (HPLC)-produced water is not acceptable] **(Note: the equivalent of ASTM Type II water can be processed on-site by using a mobile deionization/organic filtration system)**;
- pesticide-grade or better methanol or, where required by state or region, isopropanol **(Note: the use of methanol is preferred to isopropanol because of the potential for generation of acetone as a photodegradation product of isopropanol)**;
- gloves, goggles, and other protective clothing as specified in the site-specific Health and Safety Plan; and
- steam cleaner.

5.0 PROCEDURES

5.1 GENERAL PROCEDURE

Before samples are collected, the equipment used to collect water, soil, sediment, and other samples will be decontaminated by the following method.

STANDARD OPERATING PROCEDURE NO.4
FIELD EQUIPMENT DECONTAMINATION

1.0 OBJECTIVE

The objective of this procedure is to describe the proper procedures for decontaminating sampling equipment used to perform field investigations.

2.0 BACKGROUND

Decontamination of field equipment is necessary to ensure that chemical analyses reflect actual concentrations at sampling locations by maintaining the quality of samples and preventing cross-contamination. Further, decontamination reduces the health hazards to field personnel and prevents the spread of contaminants off-site.

3.0 RESPONSIBILITIES

Site Manager: The Site Manager, or Field Team Leader, is responsible for ensuring that field activities are completed to meet the project objectives, are conducted in accordance with the project plans and requirements, and that all activities are performed according to the respective procedures. The Site Manager is responsible for ensuring that all site personnel are trained in the procedures, that the procedures are adhered to, and that all activities are documented.

Field Team: All members of the field team (samplers, technicians, field geologists, engineers, etc.) are responsible for understanding and implementing this field procedure as well as ensuring that all of the team members also perform in accordance with this procedure.

It is the responsibility of all field personnel to identify, document, and submit recommendations to improve the quality, usability, and implementability of this procedure.

1. Set up a decontamination line on plastic sheeting or on a table covered by aluminum foil (shiny side away from equipment). The decontamination area should progress from "dirty" to "clean" and end with an area for drying equipment. At a minimum, clean plastic sheeting must be used to cover the ground, and plastic sheeting or aluminum foil must cover tables or other surfaces where decontaminated equipment is to be placed;
2. Dislodge as much loose dirt as possible from equipment before beginning the decontamination process. Wash the item thoroughly in a bucket or trough of soapy water. Use a stiff-bristle brush to dislodge any clinging dirt. Disassemble any items that might trap contaminants internally before washing;
3. Rinse in second bucket or trough containing tap water. Rinse water should be replaced as necessary (generally when water is cloudy);
4. Repeat step 3 in a separate bucket or trough (optional);
5. Using a hand sprayer, rinse the item with ASTM Type II or equivalent water over a separate bucket;
6. Using a hand sprayer, rinse the item with methanol or isopropanol, whichever is appropriate, over a separate bucket;
7. If the equipment will have time to fully air dry before its next use, allow to air dry. If the equipment will not be allowed to fully air dry, repeat step 5 before reassembling or using any equipment;
8. If equipment will not be used immediately after drying, wrap in aluminum foil (shiny side out) for storage and transport;
9. Record decontamination protocol, equipment types, and date in the appropriate logbook at each occurrence; and
10. After decontamination activities are complete, collect all contaminated waters, solvents, plastic sheeting, aluminum foil, disposable gloves, boots, and clothing. Place contaminated items in properly labeled drums for disposal. Liquids and solids must be drummed separately.

5.2 DOWNHOLE AND HEAVY EQUIPMENT

Downhole equipment consists of nonsampling tools such as hollow-stem augers, drill pipe, bits, casing, and screen. Drill rigs, backhoes, and other heavy machinery are also included. Equipment necessary to complete decontamination procedures includes:

- plastic sheeting;
- metal, wooden, or plastic sawhorses or other stands;
- laboratory-grade detergent (phosphate free);
- steam cleaner;
- stiff-bristle brushes;
- 2- to 5-gal manual pump sprayer (pump sprayer must be compatible with the solution used);
- deionized, organic-free water (ASTM Type II or equivalent) (HPLC-produced water is not acceptable); and
- gloves, goggles, boots, and other protective clothing as specified in the site-specific Work Plan.

Before drilling, sampling, excavating, or leaving the site, all drilling equipment used in field sampling activities must be decontaminated. All downhole augering, drilling, and sampling equipment shall be sandblasted (off-site) if it is new, painted equipment (such as split spoons or auger flights) or exhibits build-up of rust or caked material. Heavy equipment not directly used for sampling will be decontaminated at a designated area designed to contain decontamination wastes and waters. The following steps must be taken when decontaminating this equipment:

1. Set up a decontamination pad that is large enough to fully contain the equipment to be cleaned. If practical, a centralized decontamination area should be established. This area should be set up to contain contaminated rinse waters and may be constructed using one or more layers of heavy plastic sheeting with bermed sides, a lined excavated pit, or a bermed concrete or asphalt pad. The decontamination area must be constructed so that fluids can be easily pumped from the area to holding containers;
2. Set up a "clean" area upwind of the decontamination area to receive cleaned equipment for air drying. At a minimum, clean plastic sheeting must be used to cover surfaces on which decontaminated equipment is to be placed;
3. Don personal protective equipment as specified in the site-specific Health and Safety Plan before beginning cleaning activities;
4. For heavy equipment, spray areas exposed to contaminated soil using steam-spray unit. Be sure to spray down all surfaces, including the undercarriage. It is also good practice to clean the motor, hydraulic lift, oil fill, and fuel tank area to avoid introducing contamination at the work site;

5. For smaller equipment such as augers, place the objects to be cleaned on metal or plastic-covered wooden sawhorses or supports. Using the steam-spray unit, spray the contaminated equipment. Be sure to spray inside corners and gaps especially well using a brush, if necessary, to dislodge dirt;
6. For steps 4 and 5, aim the sprayer downward as much as possible to avoid spraying outside the decontamination area;
7. If the condition of downhole or heavy equipment warrants using hot soapy water in the steam-spray unit, rinse the equipment with clean, clear tap water following the steam spray. If using steam, the rinse is not necessary if the steam does not contain a detergent;
8. Remove the equipment from the decontamination area to the "clean" area to dry;
9. Record decontamination protocol, equipment types, and date in the appropriate logbook; and
10. After decontamination procedures are complete, or any time the decontamination fluids fill the bermed or contained area, collect all decontamination fluids and transfer them to appropriate containers. Place all plastic and personal protective equipment into appropriate containers. All containers must be labeled properly for disposal. Liquids and solids must be stored separately.

5.3 PUMPS AND PUMP ASSEMBLIES

Any pump in which potentially contaminated fluids come into contact with any part of the pump equipment requires decontamination. This requirement does not include peristaltic pumps. Dedicated tubing should be used for peristaltic pumps so decontamination will not be needed. If the tubing is to be reused, it must be properly decontaminated. Equipment necessary to complete decontamination procedures includes:

- ASTM Type II water;
- plastic sheeting;
- sufficient containers, two for decontamination procedure and one for waste water;
- laboratory-grade detergent (phosphate free); and
- gloves, goggles, boots, and other protective clothing as specified in the site-specific Work Plan.

Following the use of a pump for development, purging, and/or sampling, the pump should be decontaminated by the following method.

1. Set up containers in a line on the plastic;
2. Add potable water with detergent to the first container; add potable water alone to the second container. There should be sufficient water to accomplish the decontamination procedure in each container; **(Note: before using pumps, check state and regional guidance on the use of a detergent rinse. Detergent rinse of pumps is not allowed in all areas)**
3. Place one container close enough to the decontamination area to collect the spent decontamination fluids;
4. Place the pump in the first container, and pump enough water through it to equal at least three pump-and-pump-hose volumes. Pump the water into the waste drum. Move the pump to the second container and repeat. Rinse out and fill the second container with ASTM Type II water and repeat again;
5. Record decontamination protocol, equipment types, and date in the appropriate logbook; and
6. After decontamination activities are complete, collect all contaminated water; solvents; plastic sheeting; aluminum foil; and disposable gloves, boots, and clothing. Place contaminated items in properly labeled drums for disposal. Liquids and solids must be drummed separately.

6.0 RESTRICTIONS AND LIMITATIONS

Filtering of samples, when required, should be done in the field as quickly as possible. The sample shall be preserved immediately after filtration. Three basic filter systems are typically used: an in-line disposable filter, an inert gas over-pressure filtration system, and the vacuum filtration system. For systems where disposable filters are used, decontamination is not required. The filters should be discarded after the desired sample is obtained. For reusable systems, decontamination procedures for sampling equipment are found in Section 4.

STANDARD OPERATING PROCEDURE NO. 5
DIRECT PUSH TECHNOLOGY OPERATION

1.0 OBJECTIVE

The objective of this procedure is to define the techniques and requirements for the use and operation of the Direct Push Technology (i.e., Geoprobe®) hydraulically powered percussion/probing machine.

2.0 BACKGROUND

The Direct Push equipment is a vehicle-mounted, hydraulically powered, percussion/probing machine manufactured by Geoprobe Systems, Salina, Kansas. The unit uses direct push and percussion hollow steel rods with various adapters designed to collect soil gas, soil, and/or groundwater samples. These samples are used to characterize the horizontal and vertical extent of soil and/or groundwater contamination. The system can be used under any conditions amenable to hollow-stem-auger drilling. This screening method is a cost-effective alternative to traditional subsurface investigative methods. From 15 to 25 soil gas, soil, or groundwater samples can be collected in a day.

The samples commonly are analyzed using a field gas chromatograph for rapid analytical turnaround time. The traditional investigative approach is to use an auger drill rig and a fixed-base analytical laboratory. By using the system in combination with the appropriate field analytical equipment (gas chromatograph/mass spectrometer, atomic absorption, x-ray fluorescence, immunoassay, etc.), the sampling plan can be periodically adjusted in the field to ensure that the vertical and lateral extent of soil and/or groundwater contamination is determined before demobilization. Rapid analytical results are available from the field laboratory. The traditional approach normally requires several field efforts to fully characterize a site.

The probe sampling requires the temporary installation of hollow steel rods into the unsaturated soil or the saturated water table zone. Static forces are able to push the probe to depths of more than 40 ft in some soils. With the addition of percussion to the static force, probes can be driven to depths in excess of 100 ft. The Direct Push equipment also has the capability to install a permanent stainless steel groundwater sampling point called a microwell.

The advantages of the Direct Push Technology are:

- lower cost;
- ease of mobilization;
- rapid sample collection;
- absence of borehole cuttings, thus minimizing investigation-derived waste;
- ability to collect undisturbed soil and groundwater samples without constructing permanent monitoring wells;
- access to much greater depths than those achieved with hand-driven probing equipment; and
- ability to perform a downhole resistivity geophysical survey.

3.0 RESPONSIBILITIES

Site Manager: The Site Manager, or Field Team Leader, is responsible for ensuring that field activities are completed to meet the project objectives, are conducted in accordance with the project plans and requirements, and that all activities are performed according to the respective procedures. The Site Manager is responsible for ensuring that all site personnel are trained in the procedures, that the procedures are adhered to, and that all activities are documented.

Field Team: All members of the field team (samplers, technicians, field geologists, engineers, etc.) are responsible for understanding and implementing this field procedure as well as ensuring that all of the team members also perform in accordance with this procedure.

It is the responsibility of all field personnel to identify, document, and submit recommendations to improve the quality, usability, and implementability of this procedure.

4.0 REQUIRED EQUIPMENT

4.1 DECONTAMINATION EQUIPMENT

The following decontamination equipment is required:

- plastic buckets and/or troughs;

- laboratory-grade detergent (phosphate free);
- high-pressure hot water cleaner;
- stiff bristle brushes capable of cleaning the inside and outside of equipment;
- Teflon sprayers or wash bottles, or 2- to 5-gal Teflon configuration manual pump sprayer;
- plastic sheeting;
- disposable wipes or rags;
- aluminum foil;
- potable water;
- deionized, organic-free water [American Society for Testing and Materials (ASTM) Type II or equivalent];
- pesticide-grade or better methanol, or pesticide-grade or better isopropanol if required by the state or region **(Note: the use of methanol is preferred to isopropanol because of the potential for generation of acetone as a photodegradation product of isopropanol)**; and
- latex gloves, goggles, and other protective clothing as specified in the site-specific Health and Safety Plan.

4.2 PROBING EQUIPMENT

The following equipment is required:

- heavy-duty, four-wheel-drive pickup or van;
- rear-mounted hydraulic probe driving and removal system;
- rotary impact drill for asphalt/concrete penetration;
- vacuum volume pump system for soil gas sampling and groundwater purging;
- hardened steel sampling probes and accessories; and
- decontamination equipment.

4.3 PERMASCREEN EQUIPMENT

The following equipment is required:

- casing drive seat;
- expendable drive point;

- drive-point O-ring (per Geoprobe specification),
- prepacked screen;
- polyvinyl chloride protective casing;
- service cap;
- stainless steel casing; and
- casing O-ring (per Geoprobe specification).

4.4 SAMPLING EQUIPMENT

The following equipment is required:

- retractable soil gas points for vertical profiling;
- expendable soil gas points for discrete depth-interval sampling;
- 3/16-in. Teflon, polyethylene, or polypropylene tubing and soil gas points;
- appropriate sample containers, ice, cooler, and sample labels;
- glass soil gas bulbs with Teflon stopcocks and replaceable septa, stainless steel canister, or sample syringes;
- Tedlar bags;
- small-diameter Shelby-tube piston samplers for discrete depth soil sampling;
- extruder bracket and dowels for discharging soil;
- slotted well points for shallow groundwater sampling;
- water trap for vacuum pump purging or semivolatile sampling;
- small-diameter inertial foot-valve pumps, minibailers, or tubing bottom check valve for groundwater sample collection;
- granular or powdered bentonite;
- plastic sheeting, garbage bags, caution tape and posts;
- operator's manual;
- Sampling and Analysis Plan and Health and Safety Plan;
- field analytical equipment (gas chromatograph/mass spectrometer, atomic absorption, x-ray fluorescence, and immunoassay);
- large-bore sampler with liners;
- Permascreen; and
- water level indicator.

5.0 PROCEDURES

5.1 MOBILIZATION

Before initiating any field activities, the following items must be completed:

- each location will be checked for accessibility;
- all initial sampling locations will be staked;
- utility clearance will be completed on each location;
- each sampling point will be field located;
- the elevation of each groundwater sampling point will be surveyed;
- location and elevation data will be plotted on a map; and
- all sampling equipment will be decontaminated.

5.2 DECONTAMINATION

All downhole sampling equipment and all equipment directly contacting the samples will be decontaminated before use and between drilling locations.

5.3 SOIL GAS SAMPLING

There are three types of sampling tools that can be used for sampling soil gas: (1) sampling through probe rods using an expendable point, (2) sampling through probe rods using a retractable point, and (3) sampling through inner tubing using the postrun tubing (PRT) system. The PRT system is the preferred sampling method for the following reasons:

- increases speed and accuracy of soil gas sampling;
- eliminates problems associated with rod leakage and sample carryover;
- reduces the probe rod decontamination time;
- uses a simple design for ease of use and vacuum-tight sealing; and
- requires no management of inner tubing during probing.

5.3.1 Postrun Tubing Soil Gas Sampling Procedure

The following section describes the steps that must be followed when sampling soil gas using the PRT method.

5.3.1.1 Preparation

1. Decontaminate all parts before use following the decontamination procedures;
2. Install O-rings on the expendable point holder and the PRT adapter;
3. Check the probe rods for any obstructions and test fit the adapter with the PRT fittings on the expendable point holder; and
4. Connect the adapter to the end of the tubing; secure with Teflon tape, if necessary.

5.3.1.2 Probing

1. Drive the PRT tip configuration into the ground. Connect probe rods as necessary to reach the desired depth; and
2. Disengage the expendable point by pulling the probe rods up about 1 ft when the desired depth is reached. Remove the push cap from the top probe rod.

5.3.1.3 Connection

1. Insert the adapter end of the tubing inside the probe rods;
2. Push the tubing down the probe rods until it reaches the bottom. Leave 2 ft of tubing extending out of the top of the probe rods;
3. Twist the tubing in a **counterclockwise** direction until the adapter threads have threaded into the expendable point holder; and
4. Check the connection by pulling up lightly on the tubing.

5.3.1.4 Sampling

1. Connect the tubing and the in-line glass bulb or stainless steel canister to the vacuum pump system;

2. Purge the tubing and glass soil-gas bulb or stainless steel canister by pumping at least three probe rod and canister volumes before collecting a sample;
3. The gas flow rates will be monitored with a ball-type flow meter attached to the exit port of the vacuum pump;
4. Close the stopcocks in the glass bulb or stainless steel canister;
5. If the soil gas sample is collected with a syringe, puncture a silicon rubber segment in the evacuation line; and
6. If the soil does not yield vapor to the applied vacuum, either pull the probe rod back farther from the tip or apply a greater vacuum pressure.

5.3.1.5 Removal

1. After collecting a sample, pull up firmly on the tubing until it releases from the PRT adapter;
2. Remove the tubing from the probe rods. Dispose of the tubing;
3. Retrieve the probe rods from the ground;
4. Visually inspect the O-ring at the base of the PRT to verify a proper seal was achieved; and
5. Plug the hole as specified in Sect. 5.7 of this procedure.

5.3.1.6 Documentation

The following information will be recorded in the field gas sampling log: date and time, site and sample location, sample crew, probe/sample depth, flow rate, purge, and sample volume.

5.3.2 Vertical Profiling

Vertical profiling consists of collecting soil gas samples from various depths at a single location. The depth of the soil gas sample with the most significant response will indicate the optimum sampling depth. Vertical profiling should be done at some time during the soil gas survey. Knowledge of the subsurface lithology can also assist in determining the optimum depth to collect soil gas samples. (New tubing must be used for each sample.)

5.4 SOIL SAMPLING

The Direct Push Tecnology system has two different types of soil-sampling tools. The first type is the macrocore sampler (similar to a Shelby tube and cannot sample at a discrete depth). The second type of soil sampler is the probe drive soil sampler, which is a closed piston sampler for soil sampling at discrete depths. This type of sampler is designed to remain completely sealed while driven to a predetermined depth. Both types of samplers are pushed or driven and do not generate any cuttings.

5.4.1 Macrocore Sampler (Shelby Tube) Procedure

The macrocore sampler is similar to the Shelby tube and is used to collect continuous soil samples from the ground surface to a depth of 20 ft using the system. The sample tube is 48 in. long, 2.0 in. in diameter, and holds a 46-in. clear plastic PETG liner. The sampler can recover a 45-in.-long by 1.5-in.-diam core. Unlike the probe drive soil samplers, the macrocore sampler does not have a piston tip and cannot collect a discrete sample. The sampler is removed from the boring every 45 in. to remove the sample. If excessive hole sloughing is a problem, the large-bore soil sampler should be used to ensure that a representative sample is collected from a specified depth. The following steps must be followed when sampling soil with the macrocore sampler.

5.4.1.1 Sampling

1. Connect the drive cap to the drive head at the top end of the sampler;
2. Apply down-pressure and activate the hammer as necessary to begin sampling;
3. Add a probe rod and drive the sampler until the drive head reaches the ground surface; Do not proceed more than 48-in; and
4. To take samples at consecutive intervals, lower the sampler down the previously made hole. The sampler should inspect both the hole and sample liner for signs of sloughing.

5.4.1.2 Removal

1. Pull out the probe rods and the sampler with the system; and
2. Unscrew the cutting shoe and pull the liner out.

5.4.2 Probe Drive Soil Sampling Procedures

There are two types of probe drive soil samplers. They are the standard (Kansas sampler) and the large-bore sampler. The following chart lists the sizes available for both the standard and large-bore sampler.

Probe Drive Soil Samplers

Name of sampler	Sample tube dimensions (in.)	Core dimensions (in.)	Core recovery method	Liners	Depth capability (ft)[a]
Standard	10 by 1.125	8.75 by 0.96	Extruded	No	50
Standard	24 by 1.125	21.25 by 0.96	Extruded	No	50
Large bore	24 by 1.375	22 by 1.0625	Pulled out	Yes	30

[a] Depth capability will vary depending on lithology.

Liners are available for the large-bore sampler in PETG, brass, stainless steel, and Teflon. The PETG liners are used if the soil samples are collected for lithology only. For definitive sampling, the stainless steel liners are used. The large-bore sampler will collect 470 g of sample, which is sufficient for a definitive analysis.

The large-bore probe drive sampler is preferred over the standard sampler because it can accommodate liners, it is larger in diameter than the standard sampler and collects a larger soil sample, and the sample does not have to be extruded.

The following steps must be followed when collecting soil samples using either the standard- or the large-bore probe drive soil sampler.

5.4.2.1 Assembly

1. Decontaminate all parts before use following the decontamination procedures;
2. Assemble all of the parts as shown in the operator's manual; and
3. Replace the O-ring on the piston stop-pin each time the sampler is assembled. Make sure the pin is tightened down with a wrench.

5.4.2.2 Probing

1. Attach the assembled sampler onto the leading probe rod;
2. Drive the sampler into the ground and retighten the stop-pin; and
3. Drive the sampler to the top of the desired sampling interval.
   Note: A 12-in.-diam drive rod for initial drilling is often helpful in placing the sampler below the surface.

5.4.2.3 Stop-Pin Removal

1. Remove the drive cap and lower the extension rods down the inside diameter of the probe rods; use couplers to join rods together;
2. Attach the extension rod handle to the top extension rod and rotate the handle clockwise to remove the stop-pin; and
3. Remove the extension rods from the probe rods. The stop-pin should be attached to the last extension rod.

5.4.2.4 Sampling

1. Replace the drive can onto the top probe rod;
2. Mark the length of the sampler used on the top probe rod;
3. Drive the sampler the marked distance. Do not over-drive the sampler;
4. Remove the probe rods from the hole to recover the sampler;
5. Extrude the sample from the sampler. The standard sampler requires a machine extruder; the sampler liner with the sample is pulled out of the large-bore sampler by hand;
6. Place the extruded soil sample in the appropriate sample container. The soil sample in the large-bore sampler can be either extruded or the sample liner section ends can be capped; and

7. Label all samples completely immediately upon sampling.

5.5 GROUNDWATER SAMPLING

There are three types of well point configurations that can be used with the system to collect groundwater samples. All three types of well points are driven into the water table with the system, and a sample of the groundwater is collected through the hollow probe rods. The different well points available are:

- an expendable point (which is disconnected by pulling up on the probe rods to expose the open bore of the probe rod);
- a mill-slotted well point; and
- a screen point sampler.

The expendable point is not recommended because the sand and silt can flow up the probe rod and clog the sampling apparatus. The mill-slotted well point is not recommended in clays. It is driven with the probe rods to the desired depth and sampled (see Subsection 5.5.1.4 of this procedure) and is recommended for unconsolidated sand aquifers. The screen point sampler should be used in all other types of unconsolidated aquifers.

5.5.1 Screen Point Sampler Procedure

The screen point groundwater sampler is a 19-in. screen encased in a perforated stainless steel sleeve. Screens can be custom fabricated up to a length of 48-in. The screen section remains totally enclosed in a sheath until it is pushed out into the formation at the desired depth. Groundwater samples can be bailed from the rod bore or pumped directly from the screen section using flexible tubing, a PRT adapter, and a peristaltic pump. The following steps must be followed when using the screen point sampler.

5.5.1.1 Assembly

1. Decontaminate all parts before use following the decontamination procedures;
2. An uncontaminated screen insert should be used for each new sample; and
3. New O-rings must be installed at each O-ring location before each sample is taken; and

4. Follow the assembly procedures outlined in the operator's manual.

5.5.1.2 Probing

1. Place a drive cap on the assembled sampler and drive into the ground;
2. Continue to drive the sampler with probe rods until the sampler tip has been driven about 1 ft below the target sampling depth; and
3. Disengage the expendable drive point by pulling the rods back a distance of about 2 ft.

5.5.1.3 Exposing Screen

1. The 3/8-in. tubing affixed with a PRT adapter is lowered to the top end of the screen assembly;
2. The threads on the PRT adapter are engaged with the threads on the screen connector by pushing gently downward on the tubing and rotating it **counterclockwise;**
3. In a stable formation, it should be possible to push the screen assembly out into the open borehole by pushing down on the tubing; and
4. If the screen cannot be pushed into the open borehole with the tubing, remove the tubing and push the screen—with the extension rods inserted—down the inside of the probe rods. Care should be taken to prevent damage to the sample and probe rods.

5.5.1.4 Sampling

1. Attach a peristaltic or bladder pump (or a vacuum pump with an in-line trap) to the 3/8-in. tubing and collect a water sample. This method of sampling can be used at depths of 25 ft or less. Do not use a vacuum or peristaltic pump if sampling for volatile organic analytes. A bailer should be used in this case;
2. At depths greater than 25 ft, lower the 3/8-in. tubing equipped with a bottom check valve to the water level. By oscillating the tubing up and down, water will be pushed upward into the tubing. Remove the tubing from the probe rods and collect the sample. The 3/8-in. O.D. by 1/4-in.-I.D. well tubing recovers 9.64 mL/ft. Discard tubing after each sample is collected; and
3. A stainless steel bailer attached to clean nylon line can also be used to collect water samples. The bailer is lowered down the hollow drive rods to the water table.

5.5.1.5 Removal

1. Remove the tubing if the PRT system was used; and
2. Remove the probe rods and sampler.

5.6 PERMASCREEN WELL

A permanent sampling point, known as a Permascreen well, can be installed using the system. The well is installed using an expendable drive point attached to stainless steel casing. The casing is advanced by inserting probe rods inside the casing using the system. When the proper depth has been reached, the probe rods are removed and replaced with a prepacked stainless steel screen (7/8- in. by 24- in.). The rod(s) is then retracted so that water can enter through the screen. The advantages of the Permascreen well are:

- No drill cuttings or other investigation-derived wastes are generated during the installation of a Permascreen well;
- A Permascreen well is less expensive to install than a conventional well;
- The Permascreen well can be developed, purged, and sampled just like a conventional monitoring well; and
- The water produced during development and purging is minimal because of the small diameter (volume) of the Permascreen well.

5.6.1 Permascreen Well Installation and Sampling

The following steps must be followed when installing the Permascreen well.

5.6.1.1 Decontamination

Decontaminate all parts before use following the decontamination procedures in SOP 4.

5.6.1.2 Pilot Hole

A pilot hole is made by probing with a retractable pilot point threaded onto the end of the probe rod. The pilot hole should be pushed to within 2 to 4 ft of the planned total depth of the well.

5.6.1.3 Initial Assembly and Insertion

1. Ensure that an O-ring is in the proper slot on the expendable drive point, and insert the expendable drive point into the drive shoe;
2. Thread the point driver into a section of probe rod, and insert the probe rod (driver end first) into the casing assembly;
3. Thread the drive collar into the casing and the skirted drive cap onto the probe rod; and
4. Insert the casing assembly into the pilot hole. Do not retract the assembly before the sampling depth has been reached.

5.6.1.4 Driving

1. Drive the assembly with the system to the planned total depth; and
2. When adding probe rods and casing joints, make sure the threads are tight and the shoulder of the probe rod threads is even with, or above, the top of the drive collar.

5.6.1.5 Prepacked Screen Installation

1. Remove all probe rods from the inside of the installed casing. Reinstall the casing drive collar;
2. Attach the prepacked screen to a section of extension rod using a screen connector; and
3. Lower the screen/rod assembly down the casing until the screen reaches the bottom of the casing. Leave at least 25-in. of extension rod above the casing.

5.6.1.6 Casing Retraction

1. Remove the casing using the casing puller on the hammer of the system;
2. As the casing rises, press the extension rod handle down so that the prepacked screen remains stationary;
3. After the casing has been pulled up 24-in., rotate the handle of the extension rod **clockwise** at least six turns. Remove the extension rods from the casing; and.
4. Install a service cap on the top of the casing and install a protective casing with a locking cap and lock to prevent tampering.

5.6.1.7 Sampling

The well can be developed, purged, and sampled by using a peristaltic bladder, tubing with bottom check valve, or a bailer.

5.7 PLUGGING AND ABANDONMENT

All probed holes, whether soil gas, soil, or groundwater test holes, must be plugged and abandoned. Holes should be filled with a bentonite slurry, granular bentonite, or 3 percent bentonite cement from total depth to the surface. The plugging material can be poured into shallow holes less than 5 ft in depth. Deeper holes will require tremie placement of the plugging material. When plugging a Permascreen well, remove the screen with the extension rods and pour the plugging mixture into the casing as it is being removed.

5.8 QUALITY CONTROL

Any departure from the specified SOPs will be justified and authorized before deviating from the requirements. Deviations shall be sufficiently documented to allow repetition of the activity as actually performed.

6.0 RESTRICTIONS/LIMITATIONS

The following restrictions/limitations apply to these procedures:

- Soil gas results are a secondary indicator of other media (soil and water) contamination. The results are semiquantitative. Soil gas release is affected by many variables including soil mineralogy, temperature, barometric pressure, precipitation, and fluctuating water table;
- Actual soil and/or groundwater samples are preferred over soil gas samples; and
- The system is limited to sampling depths up to approximately 100 ft in unconsolidated, sandy soils and to shallower depths in compacted clayey or gravelly soils and tills.

STANDARD OPERATING PROCEDURE NO. 6
WELL DEVELOPMENT

1.0 OBJECTIVE

The objective of this procedure is to define the procedural requirements for developing monitoring wells. The quality control requirements for well development start on p. VI-1 of DOE/HWP-69/R2.

2.0 BACKGROUND

Monitoring wells are developed to create an effective filter pack around the well screen, to repair damage to the formation caused by drilling, to remove the "skin" from the borehole, and to remove fine-grained particles from the filter pack and the adjacent formation. When a cement-bentonite grout is used to seal the annular space, wells should not be developed for a minimum of 24 hr after completion. However, wells may be developed before grouting if conditions warrant.

There are many well development methods currently in use. Acceptable development methods for monitoring wells include:

- pumping,
- overpumping,
- surging and pumping,
- bailing,
- mechanical surging using a surge block, and
- backwashing.

The selection of the monitoring well development method to use at each site should be made based on site conditions and should follow the guidelines specified in the approved site-specific Work Plan.

Several indicator parameters of the produced water should be monitored to assist in the proper development of monitoring wells. The indicator parameters monitored should include pH

(accurate to ±.2 pH units), specific conductance (accurate to ±10%), water temperature (accurate to ±1°C), and turbidity [accurate to ±2 nephelometric turbidity units (NTUs)].

3.0 RESPONSIBILITIES

Site Manager: The Site Manager, or Field Team Leader, is responsible for ensuring that field activities are completed to meet the project objectives, are conducted in accordance with the project plans and requirements, and that all activities are performed according to the respective procedures. The Site Manager is responsible for ensuring that all site personnel are trained in the procedures, that the procedures are adhered to, and that all activities are documented.

Field Team: All members of the field team (samplers, technicians, field geologists, engineers, etc.) are responsible for understanding and implementing this field procedure as well as ensuring that all of the team members also perform in accordance with this procedure.

It is the responsibility of all field personnel to identify, document, and submit recommendations to improve the quality, usability, and implementability of this procedure.

4.0 REQUIRED EQUIPMENT

The following equipment is needed to develop a monitoring well using an approved development method:

- bailer, surge block, pump, controller, pump tubing, bailer, wire line, monofilament rope, and Teflon-coated stainless steel leader;
- power source (e.g., generator), if required;
- water level meter or weighted surveyor's tape;
- temperature, specific conductance, pH, and turbidity meters;
- personal protective equipment (PPE) as specified in the site-specific Health and Safety Plan;
- decontamination supplies, if required on-site; and
- disposal drums to contain produced water, if required.

5.0 PROCEDURES

5.1 WELL DEVELOPMENT

The following steps shall be followed when developing wells:

1. Don PPE as specified in the site-specific Health and Safety Plan;
2. Calibrate all meters in accordance with standard operating procedures and manufacturer's guidelines;
3. Open, check, and note the condition of the wellhead, including the condition of the surveyed reference mark;
4. Using decontaminated equipment, determine the depth-to-static-water level and depth to the bottom of the well (from the surveyed reference mark). Record on the appropriate field forms and in the field logbook;
5. Decontaminate and prepare the necessary equipment for developing the well and start well development;
6. For screened intervals longer than 5 ft, develop the well in 2- to 3-ft intervals from bottom to top. This will ensure proper packing compaction in the filter pack; **(Note: It is good practice to develop all screened and filter packed wells in stages)**
7. Continue well development until produced water is clear, free of suspended solids, and monitored indicator parameters have stabilized and are within the following ranges: pH ± 0.2; specific conductance $\pm 10\%$; temperature $\pm 1°C$; and turbidity 5 NTUs or lower, ± 2 NTUs. Record pertinent data in the field logbook and on the well development forms. In some cases the pH, temperature, and specific conductivity stabilize but the water remains turbid (above 5 NTU). If proper well completion and development measures have been employed and the turbidity is an artifact of the geologic materials in which the well is screened, then the use of turbidity measurements as an indicator parameter can be discontinued. Consultation with the field hydrogeologist is required regarding when to discontinue using turbidity measurements as an indicator parameter; and
8. Remove the development equipment from the well, decontaminate (as required), and clean up the site. Lock the well cover before leaving. Dispose of produced water as required by the project Work Plan.

5.2. WELL VOLUME CALCULATION

The well's volume must be calculated to estimate how many drums or other containers may be required and how many well volumes were removed.

$$7.4805 \times \left(\frac{D^2\pi}{4} \right) \times dH = \textit{volume (in gallons)}$$

where:

D = casing diameter in feet;

dH = the distance from well bottom to static water level in feet; and

$\pi = 3.1416$.

Note these data and calculations in the field logbook.

6.0 RESTRICTIONS/LIMITATIONS

Where flammable, light, nonaqueous phase liquid (LNAPL) or emulsified LNAPL is expected or known to exist on or in groundwater, use only intrinsically safe electrical devices and place portable power sources (e.g., generators) 50 ft (or more) from the wellhead and disposal drums.

Where flammable LNAPL (or emulsified LNAPL) is expected or known, monitoring well development should not start until all LNAPL is removed from the well.

STANDARD OPERATING PROCEDURE No. 7
DATA MANAGEMENT SYSTEM

1.0 OBJECTIVE

The objective of these procedures is to establish standardized protocols for the management of analytical and physical data during the Remedial Investigation (RI) at the 142nd Fighter Group, Oregon Air National Guard, Portland International Airport, Portland, Oregon.

2.0 SCOPE

Data management encompasses the receipt of analytical and physical data generated during remedial investigation activities, production and maintenance of an electronic database, and manipulation of this database for characterization of site conditions. Several software programs will be used to accomplish these tasks. Where possible, the data from one system will be imported to another to limit duplicate manual entries and minimize repetitive data checks.

A program called "Real-Time Interpretation System" (R-TIS) was developed for analysis of site conditions during the Remedial Investigation. This version of R-TIS was developed specifically for HAZWRAP and the Air National Guard. The system was designed based on conceptual models of site conditions to provide expeditious interpretation of field data as investigative activities progress.

R-TIS utilizes Microsoft™ database, spreadsheet, drawing, and word processing products under a Windows environment to run queries, generate tables and maps, and write reports. The use of R-TIS is detailed in the User Reference Manual. This manual should be used in conjunction with the procedures outlined in this SOP. A Technical Reference Manual documents system set up.

3.0 REQUIRED EQUIPMENT

The following equipment is required to implement the data mangement system:

- 486 PC with a minimum 8 MB RAM, 546K of continuous lower RAM, and sufficient disk space for requisite software, word processing, and graphics production or a 386 or 486

portable PC or laptop computer with a minimum 4 MB RAM and 150 MB hard disk capacity;

- Hewlett-Packard LaserJet Series III or IV printer with a minimum 3 MB RAM;
- Modems and associated communications software, or equivalent; and
- Fax machines

The following software and operating systems are also required:

- Microsoft® Windows and MS-DOS ver. 3.1 or higher;
- R-TIS;
- Microsoft® Access, Word, and Excel;
- An environmental data management system such as GIS\Key™, and associated software (Microsoft® FoxPro, AutoCAD®, and Quicksurf);
- A laboratory data management program such as Data Manager 2000;
- Geotechnical Graphics System (GTGS);
- Colorado® Backup and associated backup tapes (each 250 MB), or equivalent;
- PKZIP®; and
- Any text editor.

4.0 RESPONSIBILITIES

The Project Manager will serve as the Principle Point of Contact with HAZWRAP and the Base. The PM will direct the project team, including field operations, and coordinated all subcontractor and subtiers support. The PM will also be responsible to for the execution of data management and the site characterization process.

The Field Team Leader will directly supervise all field operations. Responsibilities will include planning, conducting, and overseeing all field personnel and transferring physical data to the Data Manager.

The Data Management Assistant (DMA) will be responsible for manual entry of physical data into R-TIS. The DMA will also be responsible for downloading raw analytical data from field laboratory instruments to the Data Manager 2000 for preliminary evaluation and file formatting.

The Data Management and Analytical Data Evaluation Manager (DEM) will be responsible for evaluation of analytical data and to ensure that a high quality is collected. Responsibilities will also include ensuring that proper data tracking and management are implemented to achieve a high level of project data accuracy. The DEM will prepare technical memorandums for real-time analysis of site conditions, report reproduction, and system seciurtiy.

5.0 PROCEDURE

Physical data will be collected and recorded on field forms by the Field Team Leader. This data will include survey coordinates, well construction details, sample tracking information, and sample location data. Following his/her review of the data, the Field Team Leader will process copies of the field forms to the Data Management Assistant for manual enter into R-TIS.

Samples obtained for chemical analysis will be collected in containers that are prelabelled with bar codes. The bar codes can be scanned in the laboratory to enable electronic tracking of samples from collection through chemical analysis.

Volatile and semi-volatile organic data generated by the field laboratory will be downloaded from the instruments to an ASCII file and uploaded into Data Manager 2000 for preliminary evaluation and file formatting. Inorganic files will be edited for extraneous information, such as duplicate injection results and instrument calibration data, using a text editor before uploading to Data Manager 2000. Selected analytical data, including sample ID, test results, detection limits, and sample collection dates, will then be downloaded to an ASCII file and the file will be submitted to the DEM. The DEM will track receipt of the analytical data and confirm transfer with the DMA.

Analytical data generated by a fixed-base laboratory, if used, will be formatted in Microsoft® Excel according to pre-assigned specifications and electronically transmitted to the DMA within seven days of receipt of samples.

The DMA will import the field analytical data into R-TIS, check the accuracy of physical data entry, and transmit to the Field Team Leader and the PM the following information within eight hours of receipt of the data:

- A summary table of contaminant hits relative to action levels or background data;

- Any figures illustrating contaminant locations, as necessary; and
- Recommendations regarding necessity of secondary samples and placement thereof.

A complete report of analytical data will be mailed to the field office daily or on an as-needed basis via overnight courier. Technical memorandums summarizing site conditions will be transmitted to HAZWRAP weekly or at the completion of field activities at individual sites.

Field and laboratory data will be evaluated following completion of the field effort. Any changes to the field analytical data will be performed by the DEM. Evalution of fixed-base laboratory data will be performed on copies of the electronic files received from the laboratory.

All evaluated analytical and physical data will be imported to GIS\Key™ for final interpretation and preparation of applicable deliverables including, as necessary:

- Groundwater flow nets;
- Chemical isopleth plans and cross sections;
- Chemical concentration graphs;
- Summary tables of contaminant concentrations which exceed action levels or site background values; and
- Comprehensive analytical data reports.

Boring logs will be constructed using GIS\Key™ or GTGS software. The data will be entered manually with the exception of survey data which can be uploaded to GIS\Key™ from R-TIS.

6.0 VALIDATION AND VERIFICATION

Validation and verification (V&V) of the data management system will be implemented to ensure data integrity and security. Procedures for V&V will include the following:

- The data management system will be tested to ensure that all forms and procedures operate according to specifications and that all data are properly updated or retained based on specified requirements. Post development and user-testing of the system will be conducted prior to start-up of the field effort. Final testing will be conducted at the site using method detection limit

study data generated from the laboratory instruments. The data transfer system will be tested before initiation of actual field activities to ensure system performance;

- Analytical data will be password-protected. Data interpretation screens will access read-only files;

- The analytical data transmitted to R-TIS will be copied to a floppy or removable hard disk drive as a backup in the unlikely event of a system failure; and

- R-TIS will be backed-up nightly to a minimum 250 MB tape backup unit using Colorado® Backup software. This operation will be performed automatically. The backup tape will be removed at the end of the work day and taken home by the Technical Lead. When that tape is removed, another tape will be installed. There will be one tape for each workday. The most current tape will always reside outside the office. GIS\Key™ files will be backed up to 3.5 in disks as needed using PKZIP®.

THIS PAGE INTENTIONALLY LEFT BLANK

STANDARD OPERATING PROCEDURE NO. 8
SOIL GAS SAMPLING AND MEASUREMENT OF OXYGEN AND CARBON DIOXIDE

1.0 OBJECTIVE

The objective of this procedure is to supply the procedures needed to conduct soil gas sampling for oxygen (O_2) and carbon dioxide (CO_2). The concentration of O_2 and CO_2 in soils gas will be measured using a Bacharach LEL-02-PPM or equivalent meter for O_2 measurements and a Riken RI-411 or equivalent meter for CO_2 measurements.

2.0 BACKGROUND

O_2 concentrations in soil gas may be used as an indication of the ability of the natural environment to sustain aerobic biodegration and the level of CO_2 may indicate natural degration of aerobically biodegradable compounds occurring at the site.

3.0 RESPONSIBILITIES

Site Manager: The Site Manager, or Field Team Leader, is responsible for ensuring that field activities are completed to meet the project objectives, are conducted in accordance with the project plans and requirements, and that all activities are performed according to the respective procedures. The Site Manager is responsible for ensuring that all site personnel are trained in the procedures, that the procedures, that the procedures are adhered to and that all activities are documented.

Field Team: All members of the field team (samplers, technicians, field geologists, engineers, etc) are responsible for understanding and implementing this field procedure as well as ensuring that all of the team members also perform in accordance with this procedure).

It is the responsibility of all field personnel to identify, document, and submit recommendations to improve the quality, usability, and implementability of this procedure.

4.0 REQUIRED EQUIPMENT

The following equipment is required to measure O_2 levels in soil gas.

GasTech Model 1314 O_2-LEL Monitor (or equivalent) with O_2 probe
rechargeable Ni-cad batteries with charger
hydrophobic filter
Tygon tubing
flow regulator

1L Tedlar bags
certified O_2 gas standards (0% O_2 and 25% O_2).

The following equipment is required to measure CO_2 levels in soil gas.

Riken I-411A CO_2 Analyzer (or equivalent) with CO_2 probe
"D" size batteries
Tygon tubing
flow regulator
1L Tedlar bags
certified gas standards (0 ppm CO_2 and 2000 ppm CO_2)

5.0 CALIBRATION

The instruments will be turned on and equilibrated for at least 30 minutes before conducting calibration. The sampling pump of the instrument will be checked to ensure that it is functioning. Low flow of the sampling pump may indicate that the battery level is low or that some fines are trapped in the pump or tubing. Any flow or instrument power supply problems will be corrected following manufacturer's instructions before calibration is conducted.

Meters will be calibrated each day prior to use against purchased CO_2 and O_2 calibration standards. The standards have been selected to bracket the expected concentration range of the soil gas to be samples. Calibration will be conducted using the following procedure:

> Fill a evacuated Tedlar bags with CO_2 calibration gases. Close the valve on each Tedlar bag. Connect the inlet nozzle of the CO_2 instrument probe to the highest concentration standard. Calibrate the instrument following manufacturers instructions. Remove the Tedlar bag containing the highest concentration of CO_2 from the instrument probe. Connect the zero air and calibrate following manufactures instructions.

Repeat the process for the O_2 meter using O_2 calibration gas standards.

6.0 SAMPLE COLLECTION

Soil gas sampling will be collected using small diameter (approximately 5/8-inch outer diameter) stainless steel probes (KVA Associates or equivalent) with a slotted well point assembly. Probes will be hand driven at the locations specified by the Field Team Leader. The maximum depth for hand-driven probes will typically be 10-15 ft, depending on soil texture. In some dense slits or clays, penetration of the soil gas probe will be less, while in some unconsolidated sands, deeper penetration of the soil gas probe may be possible. Prior to sampling the soil gas probes will be

purged with a sample pump.

7.0 SAMPLE MEASUREMENT

A calibrated CO_2 or O_2 meter will be connected into the sampling train and the soil gas concentration will be monitored until the concentrations stabilize. The stable concentration will be recorded. Stabilization may not be possible if shallow soil gas samples are collected as atmospheric air may be drawn into the probe and produce false readings When shallow soil gas samples re collected, air withdraw will be kept to a minimum.

8.0 DATA REPORTING

All calibration and measurement results will be reported on a standardized form (Attachment). All field team members conducting field soil gas measurements will be required to complete and sign the attached form for every measurement taken.

CARCINOGENICITY: NTP: YES IARC: YES Z LIST: NO OSHA REG: NO

EFFECTS OF OVEREXPOSURE
INHALATION MAY CAUSE HEADACHE, NAUSEA, VOMITING, DIZZINESS, NARCOSIS,
SUFFOCATION, LOWER BLOOD PRESSURE, CENTRAL NERVOUS SYSTEM DEPRESSION.
INHALATION OF VAPORS MAY CAUSE SEVERE IRRITATION OR BURNS OF THE RESPIRATORY SYSTEM, PULMONARY EDEMA, OR LUNG INFLAMMATION. LIQUID MAY BE IRRITATING TO SKIN AND EYES. PROLONGED SKIN CONTACT

MAY RESULT IN DERMATITIS. EYE CONTACT MAY RESULT IN TEMPORARY CORNEAL DAMAGE. INGESTION MAY CAUSE NAUSEA, VOMITING, HEADACHES, DIZZINESS, GASTRO-INTESTINAL IRRITATION, BLURRED VISION, LOWERING OF BLOOD PRESSURE. IRREVERSIBLE INJURY TO BLOOD FORMING TISSUE MAY RESULT FROM CHRONIC LOW LEVEL EXPOSURE.

TARGET ORGANS
BLOOD, CENTRAL NERVOUS SYSTEM, EYES, SKIN, BONE MARROW, RESPIRATORY SYSTEM

MEDICAL CONDITIONS GENERALLY AGGRAVATED BY EXPOSURE
NONE IDENTIFIED

ROUTES OF ENTRY
INGESTION, INHALATION, EYE CONTACT, SKIN CONTACT, ABSORPTION

EMERGENCY AND FIRST AID PROCEDURES
CALL A PHYSICIAN.
IF SWALLOWED, DO NOT INDUCE VOMITING.
IF INHALED, REMOVE TO FRESH AIR. IF NOT BREATHING, GIVE ARTIFICIAL RESPIRATION. IF BREATHING IS DIFFICULT, GIVE OXYGEN.
IN CASE OF CONTACT, IMMEDIATELY FLUSH EYES OR SKIN WITH PLENTY OF WATER FOR
AT LEAST 15 MINUTES.

---

6 - REACTIVITY DATA

STABILITY: STABLE HAZARDOUS POLYMERIZATION: WILL NOT OCCUR

CONDITIONS TO AVOID: HEAT, FLAME, OTHER SOURCES OF IGNITION

INCOMPATIBLES: STRONG OXIDIZING AGENTS, SULFURIC ACID, NITRIC ACID

DECOMPOSITION PRODUCTS: CARBON MONOXIDE, CARBON DIOXIDE

7 - SPILL AND DISPOSAL PROCEDURES

STEPS TO BE TAKEN IN THE EVENT OF A SPILL OR DISCHARGE:

WEAR SELF-CONTAINED BREATHING APPARATUS AND FULL PROTECTIVE CLOTHING. SHUT OFF IGNITION SOURCES; NO FLARES, SMOKING OR FLAMES IN AREA. STOP LEAK IF YOU CAN DO SO WITHOUT RISK. USE WATER SPRAY TO REDUCE VAPORS. TAKE UP WITH SAND OR OTHER NON-COMBUSTIBLE ABSORBENT MATERIAL AND PLACE INTO CONTAINER FOR LATER DISPOSAL. FLUSH AREA WITH WATER.

J. T. BAKER SOLUSORB(R) SOLVENT ADSORBENT IS RECOMMENDED FOR SPILLS OF THIS PRODUCT.

DISPOSAL PROCEDURE — DISPOSE IN ACCORDANCE WITH ALL APPLICABLE FEDERAL, STATE, AND LOCAL ENVIRONMENTAL REGULATIONS.

EPA HAZARDOUS WASTE NUMBER: U019 (TOXIC WASTE)

8 - PROTECTIVE EQUIPMENT

VENTILATION: USE GENERAL OR LOCAL EXHAUST VENTILATION TO MEET TLV REQUIREMENTS.

RESPIRATORY PROTECTION: RESPIRATORY PROTECTION REQUIRED IF AIRBORNE CONCENTRATION EXCEEDS TLV. AT CONCENTRATIONS ABOVE 10 PPM, A SELF-CONTAINED BREATHING APPARATUS IS ADVISED.

EYE/SKIN PROTECTION: SAFETY GOGGLES AND FACE SHIELD, UNIFORM, PROTECTIVE SUIT, POLYVINYL ALCOHOL GLOVES ARE RECOMMENDED.

9 - STORAGE AND HANDLING PRECAUTIONS

SAF-T-DATA(TM) STORAGE COLOR CODE: RED STRIPE (STORE SEPARATELY)

SPECIAL PRECAUTIONS

BOND AND GROUND CONTAINERS WHEN TRANSFERRING LIQUID. KEEP CONTAINER TIGHTLY CLOSED. STORE IN A COOL, DRY, WELL-VENTILATED, FLAMMABLE LIQUID STORAGE AREA.

---

1 - PRODUCT IDENTIFICATION

Common Name: Ethyl Benzene
CAS Number: 100-41-4
DOT Number: UN 1175
Date: July, 1988

HAZARD SUMMARY

* Ethyl Benzene can affect you when breathed in and by passing through your skin.
* Exposure can irritate the eyes, nose and throat.
* High concentration can cause you to become dizzy, lightheaded, or to pass out. Very high levels can cause paralysis, trouble breathing and death.
* Contact can irritate the skin. Prolonged exposure can cause drying, scaling and even blistering.
* High exposure may damage the liver.
* Ethyl Benzene is a FLAMMABLE LIQUID and a FIRE HAZARD.

IDENTIFICATION

Ethyl Benzene is a colorless liquid with an aromatic odor. It is used in the production of styrene and synthetic polymers, as a solvent and as a component of automotive and aviation fuels.

HOW TO DETERMINE IF YOU ARE BEING EXPOSED

* Exposure to hazardous substances should be routinely evaluated. This may include collecting air samples. Under OSHA 1910.20, you have a legal right to obtain copies of sampling results from your employer. If you think you are experiencing any work related health problems, see a doctor trained to recognize occupational diseases. Take this Fact Sheet with you.
* ODOR THRESHOLD = 2.3 ppm.
* The odor threshold only serves as a warning of exposure. Not smelling it does not mean you are not being exposed.

WORKPLACE EXPOSURE LIMITS

OSHA: The legal airborne permissible exposure limit (PEL) is 100 ppm averaged over an 8 hour workshift.

ACGIH: The recommended airborne exposure limit is 100 ppm averaged over an 8 hour workshift and 125 ppm as a STEL (short term exposure limit).

* The above exposure limits are for air levels only. When skin contact also occurs, you may be overexposed, even though air levels are less than the limits listed above.

WAYS OF REDUCING EXPOSURE

* Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respirators should be worn.
* Wear protective work clothing.
* Wash thoroughly immediately after exposure to Ethyl Benzene and at the end of the workshift.
* Post hazard and warning information in the work area. In addition, as part of an ongoing education and training effort, communicate all information on the health and safety hazards of Ethyl Benzene to potentially exposed workers.

This Fact Sheet is a summary source of information of all potential and most severe health hazards that may result from exposure. Duration of exposure, concentration of the substance and other factors will affect your susceptibility to any of the potential effects described below.

HEALTH HAZARD INFORMATION

Acute Health Effects

The following acute (short term) health effects may occur immediately or shortly after exposure to Ethyl Benzene:

* Ethyl Benzene can irritate the eyes, nose and throat.
* Exposure to high concentrations can cause you to become dizzy, lightheaded and to pass out. Very high levels can cause trouble breathing, paralysis and death.
* Contact with Ethyl Benzene can irritate the skin.

Chronic Health Effects

The following chronic (long term) health effects can occur at some time after exposure to Ethyl Benzene and can last for months or years:

Cancer Hazard

* According to the information presently available to the New Jersey Department of Health, Ethyl Benzene has not been tested for its ability to cause cancer in animals.

Reproductive Hazard

* There is limited evidence that Ethyl Benzene may damage the developing fetus.

Other Long Term Effects

* Repeated contact can cause drying and scaling of the skin. Prolonged contact can cause blistering.
* High exposure may cause liver damage.
* This chemical has not been adequately evaluated to determine whether brain or other nerve damage could occur with repeated exposure. However, many solvents and other petroleum based chemicals have been shown to cause such damage. Effects may include reduced memory and concentration, personality changes (withdrawal, irritability), fatigue, sleep disturbances, reduced coordination, and/or effects on nerves supplying internal organs (autonomic nerves) and/or nerves to the arms and legs (weakness, "pins and needles").

MEDICAL TESTING

If symptoms develop or overexposure is suspected, the following may be useful:

* Liver function tests.
* Interview for brain effects, including recent memory, mood (irritability, withdrawal), concentration, headaches, malaise and altered sleep patterns. Consider cerebellar, autonomic and peripheral nervous system evaluation. Positive and borderline individuals should be referred for neuropsychological testing.

Any evaluation should include a careful history of past and present symptoms with an exam. Medical tests that look for damage already done are not a substitute for controlling exposure.

WORKPLACE CONTROLS AND PRACTICES

Unless a less toxic chemical can be substituted for a hazardous substance, ENGINEERING CONTROLS are the most effective way of reducing exposure. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. Isolating operations can also reduce exposure. Using respirators or protective equipment is less effective than the

controls mentioned above, but is sometimes necessary.
In evaluating the controls present in your workplace, consider: (1) how hazardous the substance is, (2) how much of the substance is released into the workplace and (3) whether harmful skin or eye contact could occur. Special controls should be in place for highly toxic chemicals or when significant skin, eye, or breathing exposures are possible.

In addition, the following controls are recommended:

* Where possible, automatically pump liquid Ethyl Benzene from drums or other storage containers to process containers.
* Before entering a confined space where Ethyl Benzene may be present, check to make sure that an explosive concentration does not exist.

Good WORK PRACTICES can help to reduce hazardous exposures. The following work practices are recommended:

* Workers whose clothing has been contaminated by Ethyl Benzene should change into clean clothing promptly.
* Contaminated work clothes should be laundered by individuals who have been informed of the hazards of exposure to Ethyl Benzene.
* If there is the possibility of skin exposure, emergency shower facilities should be provided.
* On skin contact with Ethyl Benzene, immediately wash or shower to remove the chemical. At the end of the workshift, wash any areas of the body that may have contacted Ethyl Benzene, whether or not known skin contact has occurred.
* Do not eat, smoke, or drink where Ethyl Benzene is handled, processed, or stored, since the chemical can be swallowed. Wash hands carefully before eating or smoking.

PERSONAL PROTECTIVE EQUIPMENT

WORKPLACE CONTROLS ARE BETTER THAN PERSONAL PROTECTIVE EQUIPMENT.

However, for some jobs (such as outside work, confined space entry, jobs done only once in a while, or jobs done while workplace controls are being installed), personal protective equipment may be appropriate.

The following recommendations are only guidelines and may not apply to every situation.

Clothing

* Avoid skin contact with Ethyl Benzene. Wear solvent resistant gloves and clothing. Safety equipment suppliers/ manufacturers can provide recommendations on the most protective glove/ clothing material for your operation.
* All protective clothing (suits, gloves, footwear, headgear) should be clean, available each day, and put on before work.

Eye Protection

* Wear splash proof chemical goggles and face shield when working with liquid, unless full facepiece respiratory protection is worn.

Respiratory Protection

IMPROPER USE OF RESPIRATORS IS DANGEROUS. Such equipment should only be used if the employer has a written program that takes into account workplace conditions, requirements for worker training, respirator fit testing and medical exams, as described in OSHA 1910.134.

* Where the potential exists for exposures over 100 ppm, use a MSHA/NIOSH approved respirator with an organic vapor cartridge/canister. More protection is provided by a full facepiece respirator than by a half mask respirator, and even greater protection is provided by a powered air purifying respirator.
* If while wearing a filter, cartridge or canister respirator, you can smell, taste, or otherwise detect Ethyl Benzene, or in the case of a full facepiece respirator you experience eye irritation, leave the area immediately. Check to make sure the respirator to face seal is still good. If it is, replace the filter, cartridge, or canister. If the seal is no longer good, you may need a new respirator.
* Be sure to consider all potential exposures in your workplace. You may need a combination of filters, prefilters, cartridges, or canisters to protect against different forms of a chemical (such as vapor and mist) or against a mixture of chemicals.
* Exposure to 2,000 ppm is immediately dangerous to life and health. If the possibility of exposures above 2,000 ppm exists, use a MSHA/NIOSH approved self contained breathing apparatus with a full facepiece operated in continuous flow or other positive pressure mode.

HANDLING AND STORAGE

* Prior to working with Ethyl Benzene you should be trained on

its proper handling and storage.

* Ethyl Benzene must be stored to avoid contact with STRONG OXIDIZERS since violent reactions occur.
* Sources of ignition, such as smoking and open flames, are prohibited where Ethyl Benzene is handled, used, or stored.
* Metal containers involving the transfer of 5 gallons or more of Ethyl Benzene should be grounded and bonded. Drums must be equipped with self closing valves, pressure vacuum bungs, and flame arresters.
* Use only non sparking tools and equipment, especially when opening and closing containers of Ethyl Benzene.

Hazard Rating Key: 0=minimal; 1=slight; 2=moderate; 3=serious; 4=severe

FIRE HAZARDS

* Ethyl Benzene is a FLAMMABLE LIQUID.
* Use dry chemical, CO2, water spray, or foam extinguishers.
* POISONOUS GAS IS PRODUCED IN FIRE.
* CONTAINERS MAY EXPLODE IN FIRE.
* Vapors may travel to a source of ignition and flash back.
* If employees are expected to fight fires, they must be trained and equipped as stated in OSHA 1910.156.

SPILLS AND EMERGENCIES

If Ethyl Benzene is spilled or leaked, take the following steps:

* Restrict persons not wearing protective equipment from area of spill or leak until cleanup is complete.
* Remove all ignition sources.
* Ventilate area of spill or leak.
* It may be necessary to contain and dispose of Ethyl Benzene as

a HAZARDOUS WASTE. Contact your Department of Environmental Protection (DEP) or your regional office of the federal Environmental Protection Agency (EPA) for specific recommendations.

==========

FOR LARGE SPILLS AND FIRES immediately call your fire department.

==========

FIRST AID

POISON INFORMATION

Eye Contact

* Immediately flush with large amounts of water for at least 15 minutes, occasionally lifting upper and lower lids.

Skin Contact

* Quickly remove contaminated clothing. Immediately wash contaminated skin with large amounts of soap and water.

Breathing

* Remove the person from exposure.
* Begin rescue breathing if breathing has stopped and CPR if heart action has stopped.
* Transfer promptly to a medical facility.

PHYSICAL DATA

Vapor Pressure: 7.1 mmhg at 68oF (20oC)
Flash Point: 59oF (15oC)
Water Solubility: Slightly soluble

OTHER COMMONLY USED NAMES

Chemical Name:
Benzene, Ethyl

Other Names and Formulations:
Ethylbenzol; Phenylethane.

ECOLOGICAL INFORMATION

Ethyl Benzene is a colorless, flammable liquid which is mainly used as a precursor to styrene. It is present in "mixed xylenes," which are largely derived from petroleum. Ethyl Benzene may enter the

environment from petroleum-based industrial discharges or spills.

ACUTE (SHORT-TERM) ECOLOGICAL EFFECTS

Acute toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen two to four days after animals or plants come in contact with a toxic chemical substance.

Ethyl Benzene has high acute toxicity to aquatic life. It has caused injury to various agricultural crops. Insufficient data are available to evaluate or predict the short-term effects of Ethyl Benzene to birds or land animals.

CHRONIC (LONG-TERM) ECOLOGICAL EFFECTS

Chronic toxic effects may include shortened lifespan, reproductive problems, lower fertility, and changes in appearance or behavior. Chronic effects can be seen long after first exposure(s) to a toxic chemical.

Ethyl Benzene has high chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of Ethyl Benzene to plants, birds, or land animals.

WATER SOLUBILITY

Ethyl Benzene is moderately soluble in water. Concentrations of between 1 to 1,000 milligrams will mix with a liter of water.

DISTRIBUTION AND PERSISTENCE IN THE ENVIRONMENT

Ethyl Benzene is non-persistent in water, with a half-life -due to volatilization - of less than 2 days. The half-life of a pollutant is the amount of time it takes for one-half of the chemical to be degraded. About 99.5% of Ethyl Benzene will eventually end up in air; the rest will end up in the water.

BIOACCUMULATION IN AQUATIC ORGANISMS

Some substances increase in concentration, or bioaccumulate, in living oranisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals and humans.

The concentration of Ethyl Benzene found in fish tissues is expected to be somewhat higher than the average concentration of Ethyl Benzene in the water from which the fish was taken.

EIGHT-HOUR SHIFT = 300 PPM FOR 5 MINUTES IN ANY 2 HOURS. (PEL)
CEILING = 200 PPM.

---

6 - REACTIVITY DATA

STABILITY: STABLE HAZARDOUS POLYMERIZATION: WILL NOT OCCUR

CONDITIONS TO AVOID: HEAT, FLAME, OTHER SOURCES OF IGNITION, LIGHT

INCOMPATIBLES: CHEMICALLY ACTIVE METALS, STRONG BASES, STRONG OXIDIZING AGENTS

DECOMPOSITION PRODUCTS: HYDROGEN CHLORIDE, PHOSGENE, CHLORINE, CARBON MONOXIDE, CARBON DIOXIDE

---

7 - SPILL AND DISPOSAL PROCEDURES

STEPS TO BE TAKEN IN THE EVENT OF A SPILL OR DISCHARGE
WEAR SELF-CONTAINED BREATHING APPARATUS AND FULL PROTECTIVE CLOTHING. STOP LEAK IF YOU CAN DO SO WITHOUT RISK. USE WATER SPRAY TO REDUCE VAPORS. TAKE UP WITH SAND OR OTHER

NON-COMBUSTIBLE ABSORBENT MATERIAL AND PLACE INTO CONTAINER FOR LATER DISPOSAL. FLUSH SPILL AREA WITH WATER.

DISPOSAL PROCEDURE
DISPOSE IN ACCORDANCE WITH ALL APPLICABLE FEDERAL, STATE, AND LOCAL
ENVIRONMENTAL REGULATIONS.

EPA HAZARDOUS WASTE NUMBER: U228 (TOXIC WASTE)

---

8 - PROTECTIVE EQUIPMENT

VENTILATION: USE GENERAL OR LOCAL EXHAUST VENTILATION TO MEET
TLV REQUIREMENTS.

RESPIRATORY PROTECTION: RESPIRATORY PROTECTION REQUIRED IF AIRBORNE CONCENTRATION EXCEEDS TLV. AT CONCENTRATIONS UP TO 1000 PPM, A CHEMICAL CARTRIDGE RESPIRATOR WITH ORGANIC VAPOR CARTRIDGE IS RECOMMENDED. ABOVE THIS LEVEL, A SELF-CONTAINED BREATHING APPARATUS IS RECOMMENDED.

EYE/SKIN PROTECTION: SAFETY GOGGLES AND FACE SHIELD, UNIFORM, PROTECTIVE SUIT, NEOPRENE GLOVES ARE RECOMMENDED.

---

9 - STORAGE AND HANDLING PRECAUTIONS

SAF-T-DATA(TM) STORAGE COLOR CODE: BLUE (HEALTH)

SPECIAL PRECAUTIONS
KEEP CONTAINER TIGHTLY CLOSED. STORE IN SECURE POISON AREA.

MSDS for POLYCHLORINATED BIPHENYLS

1 - PRODUCT IDENTIFICATION

Common Name: Polychlorinated Biphenyls
CAS Number: 1336-36-3
DOT Number: UN 2315
Date: May, 1989

HAZARD SUMMARY

* Polychlorinated Biphenyls can affect you when breathed in and by passing through your skin.
* Polychlorinated Biphenyls are CARCINOGENS HANDLE WITH EXTREME CAUTION.
* They may be teratogens and may damage the adult reproductive system.
* Exposure can cause an acne like skin rash (called chloracne).
* They can damage the liver.
* High exposure can damage the nervous system, causing numbness, weakness and tingling ("pins and needles") in the arms and legs.

IDENTIFICATION

Polychlorinated Biphenyls are a mixture of chemicals that are clear to yellow oily liquids or solids. They are used in insulating fluids of electrical systems.

REASON FOR CITATION

* Polychlorinated Biphenyls are on the Hazardous Substance List because they are regulated by OSHA and cited by NIOSH, DOT, IARC, NTP, DEP and EPA.
* These chemicals are on the Special Health Hazard Substance List because they are CARCINOGENS and TERATOGENS.
* Definitions are attached.

HOW TO DETERMINE IF YOU ARE BEING EXPOSED

* Exposure to hazardous substances should be routinely evaluated. This may include collecting personal and area air samples. You can obtain copies of sampling results from your employer. You have a legal right to this information under OSHA 1910.20.

* If you think you are experiencing any work related health problems, see a doctor trained to recognize occupational diseases. Take this Fact Sheet with you.

WORKPLACE EXPOSURE LIMITS

OSHA: The legal airborne permissible exposure limit (PEL) is 1 mg/m3 (42% Chlorine) and 0.5 mg/m3 (54% Chlorine) averaged over an 8 hour workshift.

NIOSH: The recommended airborne exposure limit is 0.001 mg/m3 averaged over a 10 hour workshift.

* The above exposure limits are for air levels only. When skin contact also occurs, you may be overexposed, even though air levels are less than the limits listed above.
* Polychlorinated Biphenyls are PROBABLE CANCER CAUSING AGENTS in humans. There may be no safe level of exposure to carcinogens, so all contact should be reduced to the lowest possible level.

WAYS OF REDUCING EXPOSURE

* Where possible, enclose operations and use local exhaust ventilation at the site of chemical release. If local exhaust ventilation or enclosure is not used, respirators should be worn.
* A regulated, marked area should be established where Polychlorinated Biphenyls are handled, used, or stored as recommended by NIOSH.
* Wear full body protective work clothing.
* Wash thoroughly immediately after exposure to Polychlorinated Biphenyls and on exit from the work area.
* Post hazard and warning information in the work area. In addition, as part of an ongoing education and training effort, communicate all information on the health and safety hazards of Polychlorinated Biphenyls to potentially exposed workers.

This Fact Sheet is a summary source of information of all potential and most severe health hazards that may result from exposure. Duration of exposure, concentration of the substance and other factors will affect your susceptibility to any of the potential effects described below.

HEALTH HAZARD INFORMATION

Acute Health Effects

The following acute (short term) health effects may occur immediately or shortly after exposure to Polychlorinated Biphenyls:

* Exposure to the vapor can irritate the eyes, nose and throat.
* High exposures can damage the liver.

Chronic Health Effects
The following chronic (long term) health effects can occur at some time after exposure to Polychlorinated Biphenyls and can last for months or years:

Cancer Hazard
* Polychlorinated Biphenyls are PROBABLE CARCINOGENS in humans. There is some limited evidence that they cause skin cancer in humans and they have been shown to cause liver cancer in animals.
* Many scientists believe there is no safe level of exposure to a CARCINOGEN. Such substances may also have the potential for causing reproductive damage in humans.

Reproductive Hazard
* Polychlorinated Biphenyls may be TERATOGENS in humans since they have been shown to be teratogens in animals.
* They may be passed to a child through mother's milk.
* Polychlorinated Biphenyls can affect the reproductive system of adults.

Other Long Term Effects
* Repeated exposures can cause liver damage.
* Polychlorinated Biphenyls can cause a severe acne like rash (chloracne). This may persist for years.
* High exposures can damage the nervous system, causing numbness, weakness, and tingling ("pins and needles") in the arms and legs.

MEDICAL

Medical Testing
Before beginning employment and at regular times after that, the following are recommended:

* Liver function tests.
* Serum triglycerides level.
* Exam of the skin.

If symptoms develop or overexposure is suspected, the following may

be useful:

* Blood PCB levels.
* Nerve conduction studies should be considered.

Any evaluation should include a careful history of past and present symptoms with an exam. Medical tests that look for damage already done are not a substitute for controlling exposure.

Request copies of your medical testing. You have a legal right to this information under OSHA 1910.20.

Mixed Exposures
Because more than light alcohol consumption can cause liver damage, drinking alcohol can increase the liver damage caused by Polychlorinated Biphenyls.

WORKPLACE CONTROLS AND PRACTICES

Unless a less toxic chemical can be substituted for a hazardous substance, ENGINEERING CONTROLS are the most effective way of reducing exposure. The best protection is to enclose operations and/or provide local exhaust ventilation at the site of chemical release. Isolating operations can also reduce exposure. Using respirators or protective equipment is less effective than the controls mentioned above, but is sometimes necessary.

in place for highly toxic chemicals or when significant skin, eye, or breathing exposures are possible.

In addition, the following controls are recommended:

* Where possible, automatically transfer Polychlorinated Biphenyls from drums or other storage containers to process containers.
* Specific engineering controls are recommended for this chemical by NIOSH. Refer to the NIOSH criteria document: Occupational Exposure to Polychlorinated Biphenyls #77 225.

Good WORK PRACTICES can help to reduce hazardous exposures. The following work practices are recommended:

* Workers whose clothing has been contaminated by Polychlorinated Biphenyls should change into clean clothing promptly.
* Do not take contaminated work clothes home. Family members

could be exposed.

* Contaminated work clothes should be laundered by individuals who have been informed of the hazards of exposure to Polychlorinated Biphenyls.
* If there is the possibility of skin exposure, emergency shower facilities should be provided.
* On skin contact with Polychlorinated Biphenyls, immediately wash or shower to remove the chemical. At the end of the workshift, wash any areas of the body that may have contacted Polychlorinated Biphenyls, whether or not known skin contact has occurred.
* Do not eat, smoke, or drink where Polychlorinated Biphenyls are handled, processed, or stored, since the chemicals can be swallowed. Wash hands carefully before eating or smoking.
* If solid, when vacuuming, a high efficiency particulate absolute (HEPA) filter should be used, not a standard shop vacuum.

PERSONAL PROTECTIVE EQUIPMENT

WORKPLACE CONTROLS ARE BETTER THAN PERSONAL PROTECTIVE EQUIPMENT.

However, for some jobs (such as outside work, confined space entry, jobs done only once in a while, or jobs done while workplace controls are being installed), personal protective equipment may be appropriate.

The following recommendations are only guidelines and may not apply to every situation.

Clothing

* Avoid skin contact with Polychlorinated Biphenyls. Wear protective gloves and clothing. Safety equipment suppliers/ manufacturers can provide recommendations on the most protective glove/ clothing material for your operation.
* All protective clothing (suits, gloves, footwear, headgear) should be clean, available each day, and put on before work.
* Viton is recommended as a good protective material.

Eye Protection

* Eye protection is included in the recommended respiratory protection.

Respiratory Protection

IMPROPER USE OF RESPIRATORS IS DANGEROUS. Such equipment should only be used if the employer has a written program that takes into

account workplace conditions, requirements for worker training, respirator fit testing and medical exams, as described in OSHA 1910.134.

* At any exposure level, use a MSHA/NIOSH approved supplied air respirator with a full facepiece operated in the positive pressure mode or with a full facepiece, hood, or helmet in the continuous flow mode, or use a MSHA/NIOSH approved self contained breathing apparatus with a full facepiece operated in pressure demand or other positive pressure mode.

Common Name: Polychlorinated Biphenyls

DOT Emergency Guide code: 15
CAS Number: 1336-36-3

Hazard rating	NJ DOH	NFPA
FLAMMABILITY	Not Found	Not Rated
REACTIVITY	Not Found	Not Rated

CARCINOGEN
POISONOUS GASES ARE PRODUCED IN FIRE

Hazard Rating Key: 0=minimal; 1=slight; 2=moderate; 3=serious; 4=severe

FIRE HAZARDS

* Polychlorinated Biphenyls may burn, but do not readily ignite.
* Use dry chemical, CO2, water spray, or foam extinguishers.
* POISONOUS GASES ARE PRODUCED IN FIRE, including Dioxin and Chlorinated Dibenzofurans.
* If employees are expected to fight fires, they must be trained and equipped as stated in OSHA 1910.156.

SPILLS AND EMERGENCIES

If Polychlorinated Biphenyls are spilled or leaked, take the following steps:

* Restrict persons not wearing protective equipment from area of spill or leak until clean up is complete.
* Ventilate the area of spill or leak.
* Absorb liquids in vermiculite, dry sand, earth, or a similar material and deposit in sealed containers.

* Collect powdered material in the most convenient and safe manner and deposit in sealed containers.
* It may be necessary to contain and dispose of Polychlorinated Biphenyls as a HAZARDOUS WASTE. Contact your State Environmental Program for specific recommendations.

==========

FOR LARGE SPILLS AND FIRES immediately call your fire department.

==========

HANDLING AND STORAGE

* Prior to working with Polychlorinated Biphenyls you should be trained on their proper handling and storage.
* Store in tightly closed containers in a cool well ventilated area away from STRONG OXIDIZERS (such as CHLORINE, BROMINE, and FLUORINE).
* Polychlorinated Biphenyls should be handled only in an established, controlled, regulated area.

FIRST AID
POISON INFORMATION

Eye Contact
* Immediately flush with large amounts of water for at least 15 minutes, occasionally lifting upper and lower lids.

Skin Contact
* Quickly remove contaminated clothing. Immediately wash contaminated skin with large amounts of soap and water.

Breathing
* Remove the person from exposure.
* Begin rescue breathing if breathing has stopped and CPR if heart action has stopped.
* Transfer promptly to a medical facility.

PHYSICAL DATA

Flash Point: 383oF (195oC)
Water Solubility: Slightly soluble

Other Names and Formulations:

This Fact Sheet can be used for the following substances:

PCB 1242 (Chlorodiphenyl 42% Chlorine) CAS # 53469 21 9;
PCB 1254 (Chlorodiphenyl 54% Chlorine) CAS # 11097 69 1.

Not intended to be copied and sold for commercial purposes.

NEW JERSEY DEPARTMENT OF HEALTH
Right to Know Program
CN 368, Trenton, NJ 08625 0368

ECOLOGICAL INFORMATION

Polychlorinated biphenyls are complex mixtures of chlorobiphenyls which have been marketed for uses according to the percentage of chlorine in the mixture. The lesser chlorinated PCBs are colorless mobile liquids. Increased chlorination produces more viscous liquids, with further chlorination producing sticky resins or white powders. Because of their heat stability, PCBs were commonly used in electrical capacitors and transformers, and industrial heat transfer applications. PCBs may enter the environment from leakage from industrial and electrical equipment, from industrial discharges, spills, leaching from municipal landfills, and from previously contaminated sediments.

ACUTE (SHORT-TERM) ECOLOGICAL EFFECTS

Acute toxic effects may include the death of animals, birds, or fish, and death or low growth rate in plants. Acute effects are seen two to four days after animals or plants come in contact with a toxic chemical substance.

Polychlorinated biphenyls have high acute toxicity to aquatic life. Insufficient data are available to evaluate or predict the short-term effects of PCBs to plants, birds, or land animals.

CHRONIC (LONG-TERM) ECOLOGICAL EFFECTS

Chronic toxic effects may include shortened lifespan, reproductive problems, lower fertility, and changes in appearance or behavior. Chronic effects can be seen long after first exposure(s) to a toxic chemical.

Polychlorinated biphenyls have high chronic toxicity to aquatic life. Insufficient data are available to evaluate or predict the long-term effects of PCBs to plants, birds, or land animals.

WATER SOLUBILITY

Polychlorinated biphenyls are slightly soluble in water. Concentrations of less than 1 milligram will mix with a liter of water.

DISTRIBUTION AND PERSISTENCE IN THE ENVIRONMENT

The relative distribution of the various PCBs depends on the level of chlorination. Some PCBs will probably be highly persistent in water, with half-lives greater than 200 days. Potential PCB distribution in the various environmental compartments can have the following ranges, depending on degree of chlorination: air, 0-34%; terrestrial soils, 33-52%; water, 0-1.8%; suspended solids, 0.05-0.08%; aquatic biota, 0.02-0.03%; aquatic sediments, 30-50%.

BIOACCUMULATION IN AQUATIC ORGANISMS

Some substances increase in concentration, or bioaccumulate, in living organisms as they breathe contaminated air, drink contaminated water, or eat contaminated food. These chemicals can become concentrated in the tissues and internal organs of animals and humans.

The concentration of polychlorinated biphenyls found in fish tissues is expected to be considerably higher than the average concentration of PCBs in the water from which the fish was taken.

SUBJECT: Risk-Based Concentration Table, Fourth Quarter 1994

FROM: Roy L. Smith, Ph.D., Senior Toxicologist
Technical Support Section (3HW13)

TO: RBC Table mailing list

JAN - JULY 95

Attached is the EPA Region III risk-based concentration (RBC) table, which we have distributed quarterly to all interested parties since 1991. If you are not currently on the mailing list, but would like to be, please contact Anna Poulton (phone: 215-597-3179, fax: 215-597-9890) and give her your name, address, and phone and fax numbers. (This is the only information she needs; faxing parts of the table or cover memo is not necessary.)

IMPORTANT MESSAGE: It's once again time to re-register for the RBC table mailing list. We need to hear from you periodically to ensure that you still have an interest in the table, and that we have your correct address. If you have been on the mailing list since before October 1993, and would like to continue receiving the RBC table, please fax your request to re-register (or register for the first time) to Anna Poulton, along with any needed address or phone number changes. You need not respond if you were placed on the mailing list after October 1993, or if you are a Region III staff member. Please don't phone to re-register; we need hard copy to help justify continued funding. Thanks for your cooperation.

The table contains reference doses and carcinogenic potency slopes (obtained from IRIS through October 1, 1994, HEAST through March 1994, the Superfund Health Risk Technical Support Center, and other EPA sources) for nearly 600 chemicals. These toxicity constants have been combined with "standard" exposure scenarios to calculate RBCs - chemical concentrations corresponding to fixed levels of risk (*i.e.*, a hazard quotient of 1, or lifetime cancer risk of 10^{-6}, whichever occurs at a lower concentration) in water, air, fish tissue, and soil.

The Region III toxicologists use the table to screen sites not yet on the NPL, respond rapidly to citizen inquiries, and spot-check formal baseline risk assessments. The background materials provide the complete basis for all the calculations, with the intent of showing users exactly how the RBCs were developed. Simply put, RBCs are risk assessments run in reverse. For a single contaminant in a single medium, under standard default exposure assumptions, the RBC corresponds to the target risk or hazard quotient.

The calculations also have several important limitations. Specifically excluded from consideration are (1) transfers from soil to air and groundwater, and (2) cumulative risk from multiple contaminants or media. Also, the toxicity information in the table has been assembled by hand, and (despite extensive checking and years of use) may contain errors. It's advisable to cross-check before relying on any RfDs or CPSs in the table. If you find any errors, please

send me a note.

Lately, many callers have asked whether the risk-based concentrations can be used as valid no-action levels or cleanup levels, especially for soils.. The answer is a bit complex. First, it is important to realize that the RBC table does not constitute regulation or guidance, and should not be viewed as a substitute for a site-specific risk assessment. For sites where:

1. A single medium is contaminated;

2. A single contaminant contributes nearly all of the health risk;

3. Volatilization or leaching of that contaminant from soil is expected not to be significant;

4. The exposure scenarios used in the RBC table are appropriate for the site;

5. The fixed risk levels used in the RBC table are appropriate for the site; and

6. Risk to ecological receptors is expected not to be significant;

the risk-based concentrations would probably be protective as no-action levels or cleanup goals. However, to the extent that a site deviates from this description, as most do, the RBCs would not necessarily be appropriate.

To summarize, the table should generally not be used to (1) set cleanup or no-action levels at CERCLA or RCRA Corrective Action sites, (2) substitute for EPA guidance for preparing baseline risk assessments, or (3) determine if a waste is hazardous under RCRA.

This issue of the RBC table includes new toxicity constants and media concentrations, which are marked on the table in underlined boldface print.

I get many calls about the RBC table, but I'm often unavailable to answer the phone. Many of you have the same problem, so we play a lot of "phone tag". It's usually easier and more effective to fax me (at 215-597-9890) with your technical questions and concerns, and for me to respond by return fax. Of course, if you don't have access to a fax machine, I will also continue to respond to voice mail messages.

Attachment

Risk-Based Concentration Table
Background Information

General: Separate carcinogenic and non-carcinogenic risk-based concentrations were calculated for each compound for each pathway. The concentration in the table is the lower of the two, rounded to two significant figures. The following terms and values were used in the calculations:

Exposure variables	Value	Name
1-General:		
Carcinogenic potency slope oral (risk per mg/kg/d):	*	CPSo
Carcinogenic potency slope inhaled (risk per mg/kg/d):	*	CPSi
Reference dose oral (mg/kg/d):	*	RfDo
Reference dose inhaled (mg/kg/d):	*	RfDi
Target cancer risk:	1e-06	TR
Target hazard quotient:	1	THQ
Body weight, adult (kg):	70	BWa
Body weight, age 1-6 (kg):	15	BWc
Averaging time carcinogens (d):	25550	ATc
Averaging time non-carcinogens (d):	ED*365	ATn
Inhalation, adult (m3/d):	20	IRAa
Inhalation, child (m3/d):	12	IRAc
Inhalation factor, age-adjusted (m3-y/kg-d):	11.66	IFAadj
Tap water ingestion, adult (L/d):	2	IRWa
Tap water ingestion, age 1-6 (L/d):	1	IRWc
Tap water ingestion factor, age-adjusted (L-y/kg-d):	1.09	IFWadj
Fish ingestion (g/d):	54	IRF
Soil ingestion, adult (mg/d):	100	IRSa
Soil ingestion, age 1-6 (mg/d):	200	IRSc
Soil ingestion factor, age adjusted (mg-y/kg-d):	114.29	IFSadj
2-Residential:		
Exposure frequency (d/y):	350	EFr
Exposure duration, total (y):	30	EDtot

Exposure variables	Value	Name
Exposure duration, age 1-6 (y):	6	EDc
Volatilization factor (L/m3):	0.5	VF
3-Occupational:		
Exposure frequency (d/y):	250	EFo
Exposure duration (y):	25	EDo
* = Contaminant-specific toxicity parameters		

The priority among sources of toxicological constants was as follows: (1) IRIS, (2) HEAST, (3) HEAST alternative method, (4) EPA Superfund Health Risk Technical Support Center, (5) withdrawn from IRIS or HEAST, and (6) other EPA documents. Each source was used only if numbers from higher-priority sources were unavailable. The EPA Superfund Health Risk Technical Support Center, part of the Chemical Mixtures Branch of ECAO-Cincinnati, develops provisional RfDs and CPSs on request for contaminants not in IRIS or HEAST. These provisional values are labeled "e = EPA-ECAO provisional" in the table. It is possible they may be obsolete. If one of the "e" constants is important to a Superfund risk assessment, consider requesting, through a Regional risk assessor, a new provisional value.

Algorithms:

1. Age-adjusted factors: Because contact rates with tap water, ambient air, and residential soil are different for children and adults, carcinogenic risks during the first 30 years of life were calculated using age-adjusted factors. These factors approximated the integrated exposure from birth until age 30 by combining contact rates, body weights, and exposure durations for two age groups - small children and adults. The age-adjusted factor for soil was obtained from RAGS IB; the others were developed by analogy.

a. Air inhalation ($[m^3 \cdot y]/[kg \cdot d]$):

$$IFAadj = \frac{EDc \cdot IRAc}{BWc} + \frac{(EDtot - EDc) \cdot IRAa}{BWa}$$

b. Tap water ingestion ($[L \cdot y]/[kg \cdot d]$):

$$IFWadj = \frac{EDc \cdot IRWc}{BWc} + \frac{(EDtot - EDc) \cdot IRWa}{BWa}$$

c. Soil ingestion ([mg· y]/[kg· d]):

$$IFSadj = \frac{EDc \cdot IRSc}{BWc} + \frac{(EDtot - EDc) \cdot IRSa}{BWa}$$

2. Residential water use (μg/L). Volatilization terms were calculated only for compounds with "****" in the "VOC" column. Compounds having a Henry's Law constant greater than 10^{-5} were considered volatile. The list may be incomplete, but is unlikely to include false positives. The equations and the volatilization factor (VF, above) were obtained from RAGS IB. Oral potency slopes and reference doses were used for both oral and inhaled exposures for volatile compounds lacking inhalation values. Inhaled potency slopes were substituted for unavailable oral potency slopes only for volatile compounds; inhaled RfDs were substituted for unavailable oral RfDs for both volatile and non-volatile compounds.

a. Carcinogens: Calculations were based on combined childhood and adult exposure.

$$\frac{TR \cdot ATc \cdot 1000 \frac{\mu g}{mg}}{EFr \cdot ([VF \cdot IFAadj \cdot CPSi] + [IFWadj \cdot CPSo])}$$

b. Non-carcinogens: Calculations were based on adult exposure.

$$\frac{THQ \cdot BWa \cdot ATn \cdot 1000 \frac{\mu g}{mg}}{EFr \cdot EDtot \cdot \left(\frac{VF \cdot IRAa}{RfDi} + \frac{IRWa}{RfDo}\right)}$$

3. Air (μg/m³). Oral potency slopes and references were used where inhalation values were not available.

a. Carcinogens: Calculations were based on combined childhood and adult exposure.

$$\frac{TR \cdot ATc \cdot 1000 \frac{\mu g}{mg}}{EFr \cdot IFAadj \cdot CPSi}$$

b. Non-carcinogens: Calculations were based on adult exposure.

$$\frac{THQ \cdot RfDi \cdot BWa \cdot ATn \cdot 1000 \frac{\mu g}{mg}}{EFr \cdot EDtot \cdot IRAa}$$

4. Fish (mg/kg):

a. Carcinogens: Calculations were based on adult exposure.

$$\frac{TR \cdot BWa \cdot ATc}{EFr \cdot EDtot \cdot \frac{IRF}{1000 \frac{g}{kg}} \cdot CPSo}$$

b. Non-carcinogens: Calculations were based on adult exposure.

$$\frac{THQ \cdot RfDo \cdot BWa \cdot ATn}{EFr \cdot EDtot \cdot \frac{IRF}{1000 \frac{g}{kg}}}$$

5. Soil commercial/industrial (mg/kg): The default exposure assumption that only 50% of incidental soil ingestion occurs at work has been omitted. Calculations were based on adult occupational exposure.

a. Carcinogens:

$$\frac{TR \cdot BWa \cdot ATc}{EFo \cdot EDo \cdot \frac{IRSa}{10^6 \frac{mg}{kg}} \cdot CPSo}$$

b. Non-carcinogens:

$$\frac{THQ \cdot RfDo \cdot BWa \cdot ATn}{EFo \cdot EDo \cdot \frac{IRSa}{10^6 \frac{mg}{kg}}}$$

6. Soil residential (mg/kg):

a. Carcinogens: Calculations were based on combined childhood and adult exposure.

$$\frac{TR \cdot ATc}{EFr \cdot \frac{IFSadj}{10^6 \frac{mg}{kg}} \cdot CPSo}$$

b. Non-carcinogens: Calculations were based on childhood exposure only.

$$\frac{THQ \cdot RfDo \cdot BWc \cdot ATn}{EFr \cdot EDc \cdot \frac{IRSc}{10^6 \frac{mg}{kg}}}$$

APPENDIX G
DRAFT FINAL COMMENTS AND RESPONSES

THIS PAGE INTENTIONALLY LEFT BLANK

COMMENT RESPONSES

Guy Neal

Comment 1

Regarding IRP Site #1, elevated levels of methylene chloride in MW1-2, which appears to be cross-gradient from the IRP site. This suggests that the source of contamination in MW1-2 is not IRP Site #1, or that groundwater gradient fluctuates seasonally. My suggestion is that a contingency be added to allow for the addition of a new source location (IRP Site) if determined during the field investigation another source exists.

Response

Recommendations for further investigations will be made if results of the investigation indicate additional sources may exist. Please note that methylene chloride was detected in MW1-1, not MW1-2 as stated in the comment.

Comment 2

Regarding the on-site laboratory, this lab will be equipped to analyze VOC and SVOC using a GC/MS setup. The justification given for a mobile lab is to get "real time" results during the investigation. Based on the number of activities planned and the total number of sites to be investigated, I do not think that real-time results is critical. Work at various areas can easily be scheduled such that real-time results are not necessary, except for possibly the final stages of the investigation.

Another justification for using a mobile lab may be the price per sample savings. However, I think that competitive pricing and rapid turnaround times can be realized at a local fixed laboratory. My suggestion is to either eliminate usage of a mobile lab or to complete a cost analysis to show a true benefit of having a mobile lab on-site.

Response

In order to expedite the RI Report preparation the laboratory results will be input into a data management system that will provide "real time" mapping and allow interpretation of the data. By having real time analytical results the report preparation will occur as field work is being performed, thereby expediting the project as requested by the ANGRC.

It is unlikely that a local laboratory could provide analytical results with 24-hour turnaound times at a significantly lower cost. Additionally, integration of the laboratory results with other investigation results into the data management system can be performed much more efficiently with electronic data transfer from the mobile laboratory instruments. Based on

these factors and the resulting shorter time required to complete the RI Report we will proceed utilizing an on-site laboratory as indicated in the RI Work Plan.

Comment 3

If a mobile lab is not used, I suggest that the number of VOC and SVOC samples be re-evaluated and reduced. The landfill area and the burn pit area are two examples that a reduction in VOC and SVOC testing may be reduced.

Response

The objective of a RI is to delineate the nature and extent of contamination. In order to achieve this goal initial samples must be collected and analyzed for all potential contaminants of concern. As stated in the Work Plan, analyses that do not detect contaminants of concern during the primary phase of field work will be eliminated during the secondary phase of field work.

Comment 4

Management of the data appears to be critical to the completion of this phase of the project. When reviewing the document, it was not apparent to me that a field engineer or other qualified person would be collecting data points and analyzing to direct additional work that may be appropriate. If a person is referenced in the work plan, then disregard this suggestion.

Response

The Field Team Leader identified in the Quality Assurance Plan will be responsible for directing the field work as described in the comment. This person will be a scientist with a college degree and several years of experience directing similar investigations.

Comment 5

Overall, the work plan seem very thorough and should be adequate to achieve the goal of defining soil and groundwater contamination boundaries as they exist on the site.

Response

Thank you.

Major Rein

Comment 1

Ref. 5.0: Any time groundwater is drawn, a well start card (permit) is required by the state water resources divisions, (503) 378-8455 ext. 295 (attn: Rob Carter). After consultation w/ Rob you may find he will waive this requirement for your Geoprobe samples.

Response

Start cards will be obtained by the driller for monitoring wells installed during the RI. We have contacted Rob Carter and he indicates that we do not need start cards for the Geoprobe samples. Thank you for the information.

Comment 2

Ref. 6.2.2: Further describe the procedures used to arrive at PAGs. Please list any ARARs used in this procedure.

Response

Per USEPA guidance PAGs will be established by determining the 95th percentile concentration for each detected compound. Details on how this will be performed is attached.

Comment 3

Ref. 6.2.3: Describe your level of confidence in relying on phase I data (groundwater elev.) when deciding if you go to phase II where DNAPLs are involved. You may not see traces of DNAPLs in phase I data and elect not to go to phase II where DNAPLs may be present.

Response

Any potential source would originate at the ground surface and have to migrate through the soil and groundwater column before resting as a DNAPL on a confining layer. It is extremely unlikely that DNAPL would be present at the bottom of an aquifer while there is no detection of that compound in the overlying sediment and/or groundwater. We are very confident that groundwater samples collected at the water table will have dissolved concentrations if there is an underlying DNAPL.

Comment 4

Ref. 6.2.7: Our confidence in lab results is equally as important as your Q.C. manager's. We'd like to know acceptable ranges of Q.C. data for each level of quality (B & C) for indicators such as % recovery and relative percent difference. Simply publishing these limits would be helpful (not all regulators have the referenced HAZWRAP guide). Many times regulators require stricter Q.C. levels than the ones we use. They have no way of commenting until we give them the levels. This will avoid many conflicts and possible re-do of samples/analyses.

Response

Analytical precision, accuracy and sensitivity requirements for analytical definitive (Level C) and screening (Level B) data are presented in Tables 4.1 through 5.2 of the QAPP. Field measurement data accuracy requirements are located in Section 8 of the QAPP.

Comment 5

Ref. 6.3.1: Recommend comparing results to U.S.G.S. professional paper 1270 levels of background to rule out that our proposed background levels do not exceed those already published.

Response

Concentrations of inorganics can vary widely which is why site-specific results, when available, will supersede regional published values. Our PAGs will be based on the site-specific results.

Comment 6

Ref. 6.3.2: Reference to a prior risk assessment is questionable. State the source of the prior risk assessment and rule out that it is less stringent than current risk assessment standards (EPA/903/R-93-0001) required in section 10.

Response

The source of the prior risk assessment is identified as being after the SI. Reviewing previous risk assessments to determine if they comply with current guidelines is not recommended as this would imply that all previous decisions are subject to review and change based on current guidelines.

Comment 7

Ref. fig. 6.11: Relocate soil and groundwater sample points at the fuel dispensing stands to the edge of the pavement where spill runoff has collected.

Response

Sample points will be relocated in the field as required.

Comment 8

Ref. 9.8: Your discussions on state ARARs for soil and groundwater is incomplete. Given OAR 340-122-427 (1) and 340-40-030 (3) (a) regarding soil and groundwater, respectively, the state reserves the right to establish cleanup levels above background based on case by case oversight of risk assessments. Without oversight and subsequent approval, you cannot claim that there is any cleanup level established, at the present, or other than background.

This comment has been sent previously, in writing, dated 9 AUG 95 and confirmed verbally with DEQ, voluntary cleanup division, Mike Rosen. Please rewrite your discussion accordingly.

Response

We agree with the comment. However, at the Remedial Investigation stage development of ARARs consists largely of identifying and listing all potential requirements. ARARs are interactively evaluated throughout the CERCLA process, with input from many stakeholders. Not until development of remedial alternatives in the Feasibility Study are they conclusively identified for each proposed alternative. Therefore, language in Section 9 consistently refers to the different Standards as potential ARARs that will be considered for setting cleanup levels. There is no claim that cleanup levels have been established. We have provided the lists of Standards that will be considered in developing cleanup levels as is appropriate at this stage of the CERCLA process. (See also CERCLA Compliance with Other Laws Manual, Draft Guidance, EPA/540/G-89/89/006, August 8, 1988 page xv).

Comment 9

Ref. 11.1: Base wash racks can only be u sed if soil is brushed off, further removed with compressed air, and collected prior to arrival at the wash rack.

Response

Base wash racks will not be used for equipment decontamination. A staging area where we can set up a decon pad that will allow us to containerize all cuttings and liquid wastes is required.

Comment 10

Ref. 13: The following is a repeat of a prior comment. It is important that the generator (HAZWRAP) perform all the functions call out in this comment to insure that proper waste determinations/classifications are made:

DISPOSAL OPTION	CHARACTERIZATION METHOD
Return to Sampling Point	If analytical results for all sample elevations are ≤ surface background, then soil/groundwater can be returned to the surface sampling point.
Discharge to Sanitary Sewer	Batch Discharge Permit Requirements: pH, BOD, TSS.
Dispose of in Controlled Sanitary Landfill (Sanifill)	Complete attached "Generator's Special Waste Profile Sheet" by HAZWRAP. Signature by OANG personnel.
Dispose of in EPA TSD as Hazardous Waste	Complete attached "Hazardous Waste Profile Sheet" by HAZWRAP. Signature by ORANG personnel.

Response

The revised Section 13 was an attempt to comply with this comment while providing a simple flow diagram for field personnel to follow. Note that most of the soil cuttings will be generated during background monitoring well installation and samples from these soils will be used to establish background levels; these levels have not been determined. In order to determine how these cuttings would be handled we decided to compare values with EPA RBCs. If concentrations are below these levels the soils should not pose a threat to human health or the environment and surface disposal would be appropriate.

Groundwater background values have also not yet been established. Since most of the water will be generated while determining these values, we recommend sampling all water for the Sanitary Sewer Discharge Requirements and disposing of the water into the Sanitary Sewer

if possible. We will work closely with the Base and regulatory authorities to ensure we analyze water samples for the required analyses for making this determination.

All required paperwork for disposal of investigation derived waste will be completed by HAZWRAP for signature by the Base. Please note that the Base is the waste generator.

Calculation of Project Action Goals (Background Levels)

The following text outlines the steps necessary to determine the 95% upper tolerance limit on the background data set and the steps for comparison to background for elimination of analytes from the list of chemicals of potential concern at a site.

1. Evaluate detection limits prior to the calculation of any statistics for the background data to ensure that they are of an acceptable level for risk assessment. Also, an attempt should be made to evaluate outliers (data points that are extreme values and that do not ppear to to belong to the background distribution) and if justified, to eliminate the outliers from the background distribution prior to the calculation of the background UTL concentration.

2. Determine an upper 95% tolerance limit (UTL) concentration with 95% coverage for the distribution of the appropriate background data.

   A. Calculate the UTL concentration form the background data based on the best-fit distribution and the frequency of detection. There are three categories of data based on the frequency of detection:

      - Frequency of detection is $\geq$ 50%
      - Frequency of detection is between 0% and 50%
      - Frequency of detection is 0% (all nondetects)

   B. When the frequency of detection is $\geq$ 50%, calculate the UTL concentration according to the best-fit distribution for each analyte (normal or lognormal distribution):

      a) Test the hypothesis that the data are normally distributed using a 95% level of confidence.

      b) Test the hypothesis that the data are lognormally distributed using a 95% level of confidence.

      c) Choose the best-fit distribution based on results from (a) and (b) above.

   C. When the frequency of detection if between 0% and 50%, there is very little confidence that the background distribution can be adequately characterized (since more than half of the data points are probably reported as quantitation limits). In this situation, use the 99th percentile of the background data as teh "cutoff" for determining if the site data are above background.

   D. When the frequency of detection is 0% (all nondetects - less than the reported quantitation limit), use the largest reported quantitation limit as the "cutoff" for determining if the site data are above background.

Calculating the UTL Concentration

1) Parametric Calculation

a) *Normal*: $UTL = \bar{x} + k(s_x)$

where:

$\bar{x}$ =arithmetic mean of the background data,
k =appropriate tolerance factor for one-sided tolerance intervals (based on sample size), and
s_x =standard deviation of the background concentrations.

b) *Lognormal*: $UTL = \exp [\bar{y} + k(s_y)]$

where:

exp = e (2.718281828),
$\bar{y}$ =arithmetic mean of the logs of the background data,
k =appropriate tolerance factor for one-sided tolerance intervals (based on sample size), and
s_y =standard deviation of the logs of the background concentrations.

2) Nonparametric Calculation

For sample sizes ≤59, the nonparametric UTL concentration = maximum detected concentration (Walpole and Myers 1978).

Parameters can be found in standard statistical texts, such as "Statistical Methods for Environmental Pollution Monitoring" by Richard O. Gilbert.

3. After calculating the UTL concentration, compare the UTL concentration to the maximum detected background concentration; use the smaller of these two concentrations as the "cutoff" for determining if site data are above background. If any single detected cocnentration from the site is above the background UTL concentration, then there is evidence that the site data's distribution is different from the background data's distribution. Analytes that have all detected concentrations at or below the background UTL concentration can be eliminated from the list of chemicals of potential concern, based on comparison to background.

EXECUTIVE SUMMARY

This Feasibility Study (FS) report has been prepared for the 142nd Fighter Wing, Portland Air National Guard Base (Portland ANGB) in Portland, Oregon as part of the ongoing Remedial Investigation/Feasibility Study process.

The development of an FS represents a critical phase in the environmental investigation and cleanup process and is required when risk to human health or the environment exceeds acceptable levels. The FS report describes the process in which remedial action alternatives are developed, evaluated, and selected.

The remedy selection process ensures that statutory and administrative rule requirements are met, provides the public with a foundation on which to provide comments regarding proposed remedies, and allows regulatory agencies the ability to select or approve the most appropriate remedy for sites at which a release of a hazardous substance(s) has occurred.

The primary objectives of this FS were to:

- Develop, screen, and evaluate remedial alternatives for addressing contaminants in soil and groundwater at the Portland ANGB that may pose a threat to human health or the environment; and

- Recommend the most technically appropriate and cost-effective remedial alternatives that adequately protect human health and welfare and the environment.

The structure for this FS Report has been adapted from several formats recommended by Air National Guard (ANG), United States Environmental Protection Agency (USEPA), and Oregon State Department of Environmental Quality (ODEQ) guidance documents. The ANG includes a recommended FS structure in the document entitled, *Final Air National Guard Installation Restoration Program Investigation Protocol* (ANG 1998). The USEPA document, *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (USEPA 1988), is the most widely used and referenced guidance for the production of Remedial Investigation (RI) and FS documents. The State of Oregon document entitled, *Final Guidance for Conducting Feasibility Studies* (ODEQ 1998b), generally follows the process specified in the USEPA Guidance,

with certain variations and additional requirements. Additional requirements set by ODEQ include the evaluation of beneficial-use scenarios and hot spots.

The FS was primarily based on the cumulative results of environmental investigations conducted at the Portland ANGB between 1987 and 2000, as fully documented in the RI Report (Environmental Resources Management 2001a). These investigations identified contaminants in soil, sediment, groundwater, and surface water at 10 different Installation Restoration Program (IRP) sites at the Portland ANGB. Based on the investigation results, as well as a baseline risk assessment performed during the RI, three of the 10 IRP sites (IRP Sites 2, 9, and, 11) were determined to require full evaluation in this FS based on volatile organic compounds (VOCs) in groundwater at concentrations that pose unacceptable risk to human health.

Based on the results of the RI and on guidance provided by USEPA and ODEQ, remedial alternatives were identified and developed for each IRP site selected for further evaluation. The alternatives were then compared and evaluated as the basis for recommending the final remediation alternative for the IRP sites.

Development of Remedial Action Objectives (RAOs): RAOs provide specific goals for each affected media (i.e., soil, groundwater, etc.) at the IRP sites requiring additional remediation. These goals are typically based on achievement of a specified cleanup level or specified acceptable risk level. The RAOs for the Portland ANGB are:

- Prevent off-site migration of groundwater containing VOCs above 10^{-6} risk concentrations for individual carcinogens;
- Treat groundwater hot spots of contamination to concentrations below respective significant adverse-effect levels; and
- Prevent on-site exposure to groundwater containing VOCs above 10^{-6} risk concentrations for individual carcinogens.

Development of General Response Actions: General response actions are broadly defined as measures designed to prevent or minimize adverse environmental impacts to satisfy the RAOs. The general response actions developed for remediation of groundwater at IRP Sites 2, 9, and 11 include:

- No action;

- Institutional controls;
- Engineering controls;
- Groundwater collection, treatment, and discharge; and
- In situ groundwater treatment.

Identification and Screening of Technologies: Technologies considered capable of achieving the RAOs were identified and "screened" for further evaluation as feasible remedial alternatives. The technologies selected for further assessment were:

- No action;
- Monitoring;
- Land / Water use restrictions;
- Construction controls;
- Alternative water supplies;
- Groundwater extraction;
- In situ chemical treatment;
- In situ biological treatment;
- In situ physical treatment; and
- Monitored natural attenuation.

Development of Remedial Alternatives: Using the RAOs, general response actions, and technologies selected for further evaluation, six remedial alternatives were developed for evaluation and comparison. These alternatives included:

- *Alternative 1 – No Action.* The FS process requires consideration of the No Action Alternative. Under this alternative, no site modifications or monitoring would be implemented to prevent or eliminate human health and environmental risks.
- *Alternative 2 – Monitored Natural Attenuation.* The use of monitored natural attenuation to achieve remedial objectives relies on biological, physical, and chemical processes occurring in the environment without

artificial stimulus. Monitoring and documenting the intrinsic bioremediation element of natural attenuation is the major focus of this alternative. Under this alternative, active treatment measures would not be taken.

- *Alternative 3 – In Situ Oxidation – Potassium Permanganate/Sodium Persulfate Injection with Monitored Natural Attenuation.* This alternative involves the injection of a solution of either potassium permanganate to treat chlorinated VOCs, or sodium persulfate to treat benzene, into the contaminated zone. These materials are strong oxidants that have been shown to effectively destroy VOCs. This alternative also includes the use of monitored natural attenuation in areas with low levels of VOCs.

- *Alternative 4 – In Situ Oxidation – Ozonation with Monitored Natural Attenuation.* Ozonation involves the injection of a mixture of air and ozone gas at the bottom of the saturated zone to be treated. Ozone is a strong oxidant that has been shown to rapidly destroy VOCs. This alternative also includes the use of monitored natural attenuation in areas with low levels of VOCs.

- *Alternative 5 – Enhanced Bioremediation with Monitored Natural Attenuation.* Enhanced bioremediation involves the injection of a material that stimulates the natural biological activity of the contaminated zone. This alternative also includes the use of monitored natural attenuation in areas with low levels of VOCs.

- *Alternative 6 – In-Well Aeration with Monitored Natural Attenuation.* In-well aeration involves performing stripping of VOCs within a treatment well. Within each aerator well, water is pumped from a lower screen to the upper section of the well where it is sparged with air. The sparged water is then allowed to flow back into the soil through an upper well screen. This alternative also includes the use of monitored natural attenuation in areas with low levels of VOCs.

Each remedial alternative was evaluated for IRP Sites 2, 9, and 11. A conceptual design for each alternative at each IRP site was performed for cost estimating purposes. A detailed analysis of the remedial alternatives for the various IRP sites was performed in accordance with USEPA and ODEQ FS guidance. The criteria used for this evaluation included the overall protectiveness of human health and the environment; compliance with applicable, relevant, and appropriate requirements; long-term effectiveness and permanence; reduction of toxicity, mobility, or volume through treatment; short-term effectiveness; implementability;

reasonableness of cost; and treatment of hot spots. Following an evaluation of each alternative against the above criteria, the alternatives for the individual IRP sites were then compared.

As a result of the evaluation and comparison process, it was determined that Alternative 3, in situ oxidation using potassium permanganate combined with monitored natural attenuation, is the preferred remedial alternative for IRP Site 2. A variation of Alternative 3, using sodium persulfate rather than potassium permanganate, was selected as the preferred remedial alternative for IRP Site 9. Alternative 3 was also selected as the preferred alternative at IRP Site 11. The selection of these alternatives was based on several evaluation criteria, including the level of protectiveness of human health and the environment, effectiveness, cost reasonableness, and implementability. The preferred alternatives for IRP Sites 2, 9, and 11, as described above, best satisfy the FS evaluation criteria.

SECTION 1.0

INTRODUCTION

This Feasibility Study (FS) report has been prepared for the 142nd Fighter Wing, Portland Air National Guard Base (Portland ANGB) in Portland, Oregon as part of the ongoing Remedial Investigation/Feasibility Study (RI/FS) process. The location of the Portland ANGB is shown on Figure 1-1. The FS was conducted as part of the Air National Guard (ANG) Installation Restoration Program (IRP) under contract DAHA-90-94-D-0014 between Environmental Resources Management (ERM) and the National Guard Bureau, Department of the Army and the Air Force. The Air National Guard/Installation Restoration Program Branch (ANG/CEVR) is providing technical and project management oversight for this study on behalf of the ANG.

1.1 Purpose and Objective

The development of an FS represents a critical phase in the environmental investigation and cleanup process. As shown on Figure 1-2, the FS is a critical component of this process and is required when risk to human health or the environment exceeds acceptable levels. The FS report describes the process in which remedial action (RA) alternatives are developed, evaluated, and selected.

The remedy selection process outlined in this FS ensures that statutory and administrative rule requirements are met, provides the public with a foundation on which to provide comments on proposed remedies, and allows regulatory agencies the ability to select or approve the most appropriate remedy for sites at which a release of hazardous substances has occurred.

The primary objectives of the FS are:

- Develop and evaluate remedial alternatives for addressing contaminants in soil and groundwater at the Portland ANGB that may pose a threat to human health or the environment; and

- Recommend the most technically appropriate and cost-effective remedial alternatives that adequately protect human health, welfare, and the environment.

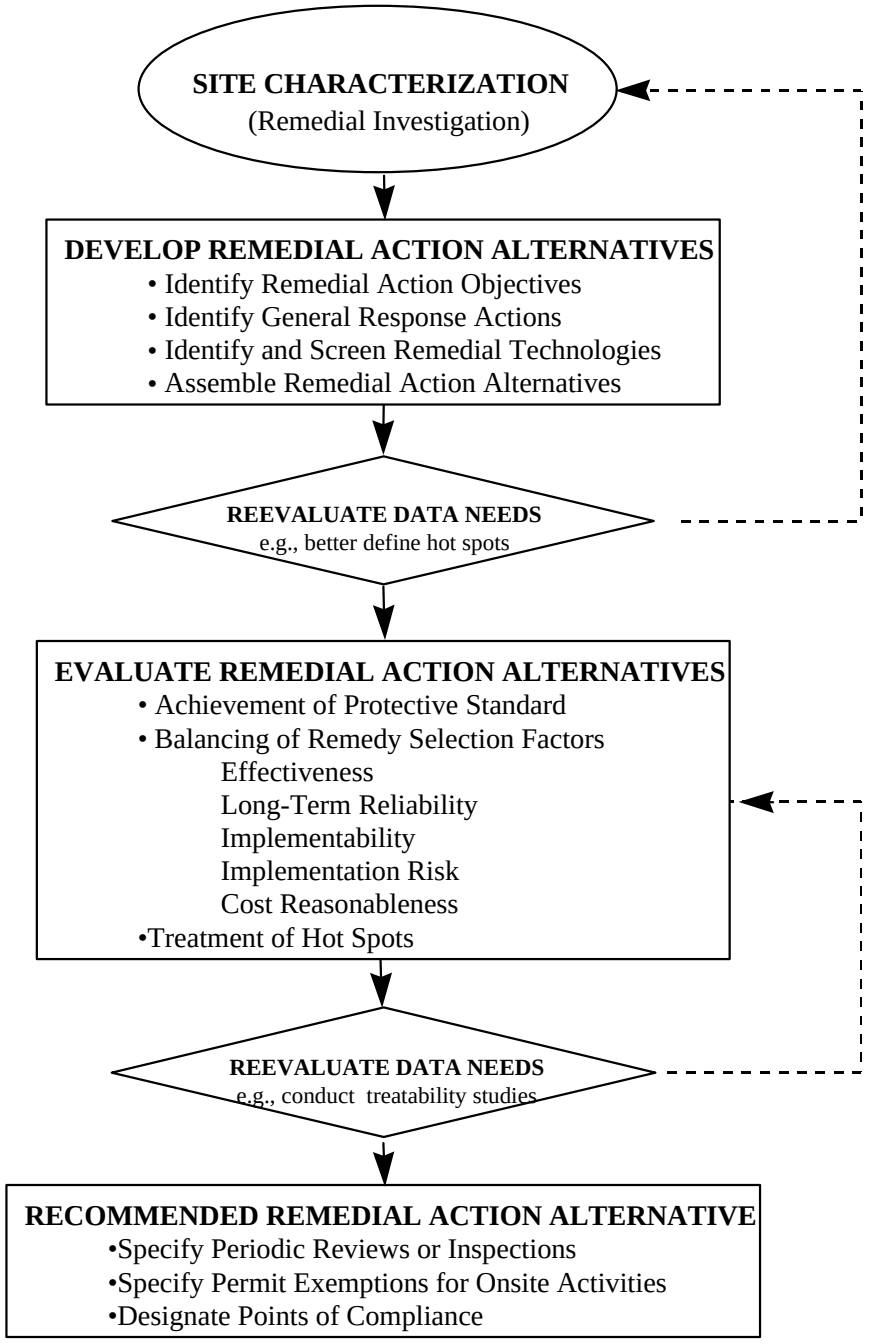
1.2 Feasibility Study Guidance

The structure for this FS report is a blend of formats recommended by ANG/CEVR, United States Environmental Protection Agency (USEPA), and Oregon State Department of Environmental Quality (ODEQ) guidance documents. ANG includes a recommended FS structure in the document entitled, *Final Air National Guard Installation Restoration Program Investigation Protocol* (ANG 1998). The USEPA document, *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (USEPA 1988), is the most widely used and referenced guidance for the production of Remedial Investigation (RI) and FS documents. The State of Oregon document entitled, *Final Guidance for Conducting Feasibility Studies* (ODEQ 1998b), generally follows the process specified in the USEPA Guidance with certain variations and additional requirements. The additional requirements set by ODEQ include the evaluation of beneficial-use scenarios and hot spots of contamination. Although the ODEQ uses different terminology than the USEPA to identify its criteria for the evaluation of remedial alternatives, both sets of standards are substantively similar.

Adjustments to the formats set by the three guidance documents described above were necessary to accommodate the inclusion of multiple IRP sites in one FS document. Beneficial-use scenarios were evaluated in the RI and summarized in Section 2.10 of this FS and used to delineate the Locality of the Facility (LOF), as required by the *Final Guidance for Conducting Beneficial Water Use Determinations at Environmental Cleanup Sites* (ODEQ 1998a). Based on the beneficial-use scenarios, the potential existence of hot spots of contamination was also evaluated in the RI, based on the ODEQ document, *Final Guidance for Identification of Hot Spots* (ODEQ 1998c), and summarized in Section 2.11 of this FS. The evaluation criteria used to compare remedial alternatives follow the USEPA guidance with the inclusion of substantive additions required by ODEQ. In accordance, the evaluation criteria, Treatment of Hot Spots, required by ODEQ was added to the list of evaluation criteria used.

1.3 Organization of Feasibility Study

The specific elements of the FS, as described in ODEQ Guidance, are diagrammed on Figure 1-3. The organization of this FS follows the main principles of this structure. This organization consists of six sections and six appendices. The contents of these sections are as follows:



- Section 1.0 presents the purpose and objective for the FS. This section also discusses the guidance documents used to select a format for this FS and a description of the elements of that format.

- Section 2.0 presents background information regarding the Portland ANGB, including a brief history and description of the Base, and a brief discussion of land use, topography, climate, sensitive receptors, geology, hydrogeology, previous environmental activity, and current IRP activities.

- Section 3.0 presents a description of each IRP site at the Portland ANGB. This description includes results of the RI that are relevant to the FS process. This information includes history and use of the site, waste disposal history, nature and extent of contamination, risk assessment results, and recommendations. The recommendations made for each IRP site presented in this section discuss the way that the individual IRP sites are treated in the FS. No further action is recommended at some IRP sites, and other IRP sites are recommended for further evaluation in this FS report.

- Section 4.0 describes the process used to develop remedial alternatives for the Portland ANGB. A discussion of the remedial action objectives (RAOs) is provided, along with a list of general response actions that includes categories of technologies expected to meet the RAOs. A series of remedial alternatives are subsequently outlined, which are based on combinations of technologies described under the general response actions.

- Section 5.0 presents a detailed analysis of the remedial alternatives for the various IRP sites. In accordance with the USEPA and ODEQ FS guidance documents, the assessment criteria used to evaluate each remedial alternative is first summarized in this section. Following an evaluation of each alternative, a comparative analysis is presented with a subsequent discussion of the preferred alternative.

- Section 6.0 presents a summary of the recommended RA alternatives for IRP Sites 2, 9, and 11, as well as a summary of the recommendations for the IRP sites not evaluated in Section 5.0. This section also includes a residual risk assessment. This assessment is used to determine the hypothetical risk remaining after completion of the recommended RA alternative at IRP Sites 2, 9, and 11.

- Section 7.0 lists the documents referenced for this FS.

A description of the appendices included as attachments to this document is provided as follows:

- Appendix A presents a description of the IRP process and fundamentals of the RI/FS program presented above and is intended to familiarize the reader with the purpose and structure of FS documents.

- Appendix B includes tables containing cost estimates for the selected remedial alternatives, including the calculations on which these estimates are based.

SECTION 2.0

PORTLAND ANGB DESCRIPTION

The Portland ANGB is immediately south of the Portland International Airport (PIA) in Portland, Oregon, between the Columbia River to the north and the Columbia Slough to the south (Figure 1-1).

The 142nd Fighter Wing is an active unit with a full-time contingency of F-15 fighter planes, crews, and support units, including active-duty ANG personnel. The major support operations at the Portland ANGB that use and dispose of hazardous wastes/materials include aircraft, vehicle, and equipment maintenance; facilities maintenance; and Petroleum, Oil, and Lubricants (POL) management. These activities generate varying quantities of waste oils, recovered fuels, and spent cleaners, solvents, and acids.

2.1 Base History

Site development began in 1936 with the placement of a large quantity of dredge material as fill in various portions of the subject property (Guthrie Slusarenko Associates 1986). The 142nd Fighter Wing began operations in 1941 at the present location of the Portland ANGB, which functioned as an Army Air Base until 1945. The Base was converted to an ANG facility in approximately 1947. Between 1950 and 1964 it was an active Air Force Base; in 1964 the Base was converted back to an ANG facility and has maintained this status to the present time (Science Applications International Corporation [SAIC] 1991).

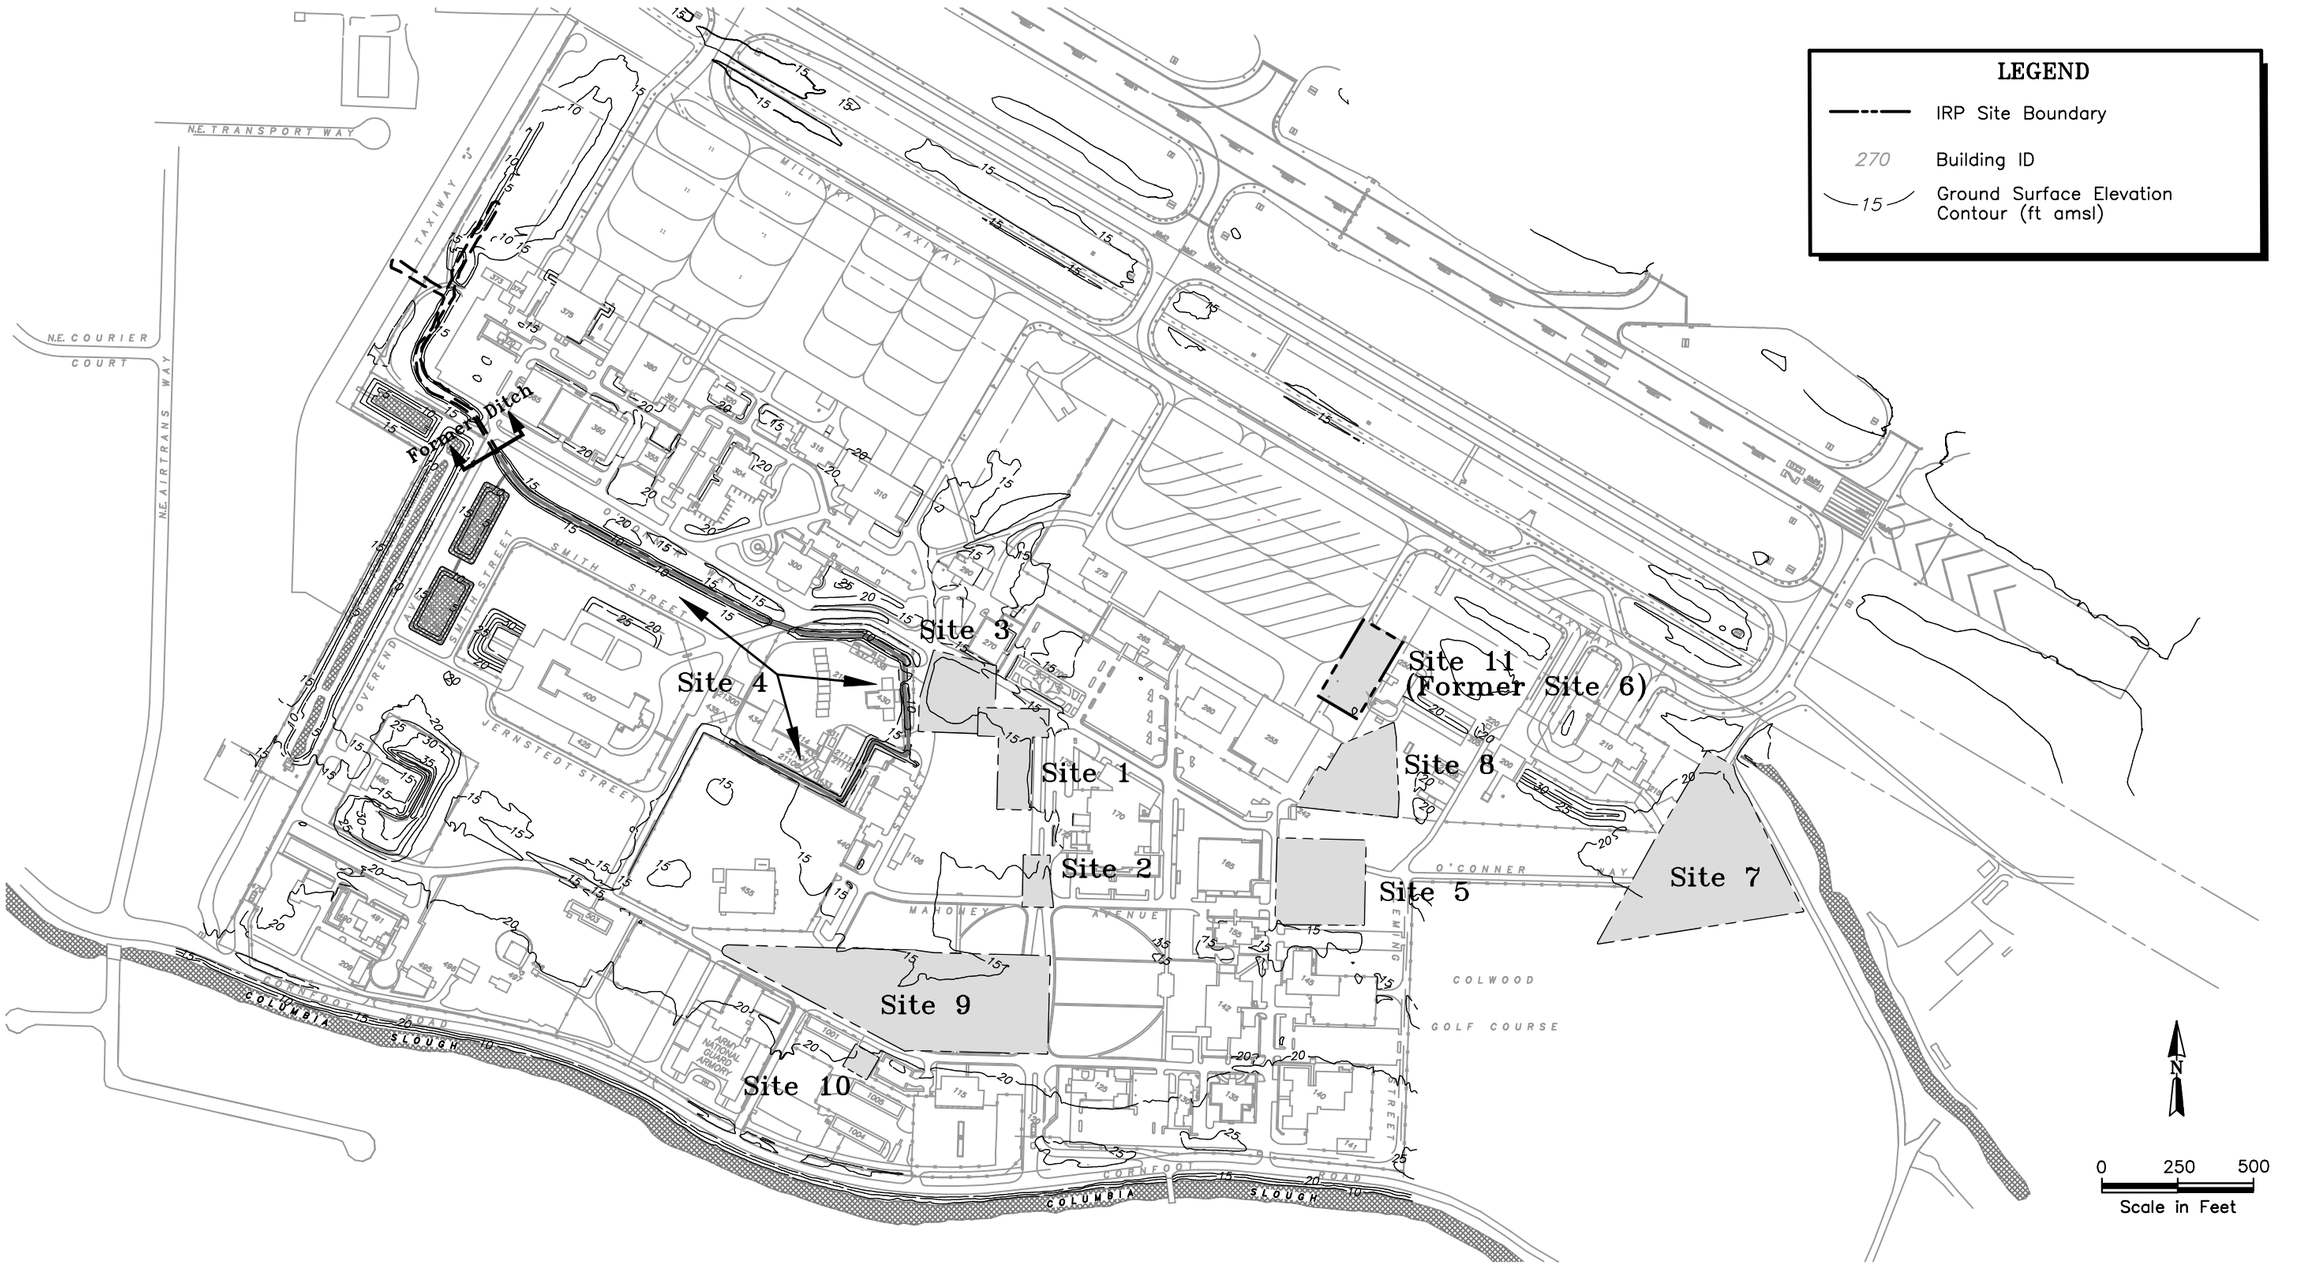
2.2 Land Use

The Base occupies approximately 245 acres of land leased from the Port of Portland. It is bordered on the west by the Riverside Country Club and the Peninsula Drainage Canal. The areas south and east of the Base are zoned for residential, industrial, and commercial use. A City of Portland municipal well field (Columbia South Shore Well Field) is southeast of the Base (Figure 1-1); the western boundary of the well field is approximately

1 mile from the Base. All of the IRP sites are within the Portland ANGB boundary, with the exception of IRP Site 7 (Burn Pit Area), which straddles the eastern Base boundary. A portion of IRP Site 7 is on Port of Portland property. Figure 2-1 shows the location of the IRP sites at the Portland ANGB. A beneficial land use description is presented in Section 2.10.4.

Land use at the Portland ANGB is industrial. Activities conducted at the Base are consistent with military base or airport usage. ANG leases the land from the Port of Portland, which operates the PIA. The Port of Portland has no plans to change the industrial land use at the Base if ANG vacates the facility (Port of Portland 2000). An expansion of the existing PIA onto the space currently occupied by the Base is the most likely scenario (Port of Portland 2000).

2.3 Topography



The Portland ANGB is situated on the Columbia River Floodplain. The ground surface across the Base is relatively flat and varies in elevation from approximately 10 to 20 feet above mean sea level. The 100-year floodplain elevation for the area surrounding the Base is 14 feet above mean sea level.

2.4 Climate

The climate in the Portland area is characterized by mild rainy winters and warm-to-hot, dry summers. Approximately 88 percent of the total annual rainfall occurs between October and May. The mean annual temperature is about 53 degrees Fahrenheit (°F), with winters averaging 40 to 50 °F and summers averaging 60 to 70 °F (SAIC 1991). The mean total annual precipitation at the PIA is 37.20 inches. The mean net annual precipitation, calculated by subtracting the mean evapotranspiration from the mean total precipitation, is 13.81 inches (Hazardous Materials Technical Center [HMTC] 1987).

2.5 Ecological Receptors

No endangered or threatened fauna or flora were identified within 1 mile of the Portland ANGB during the Preliminary Assessment (PA)

FIGURE 2-1

(HMTC 1987). However, large, open-space, grassland areas associated with the PIA complex provide some habitat for wildlife (Hoffman et al. 1996). The wildlife includes small mammals, songbirds, and raptors. Raptors have been observed along the Main Drainage Ditch and the Columbia Slough (SAIC 1991).

A more recent environmental impact statement completed in the vicinity of the PIA identified no threatened, endangered, or sensitive plants in the area. The only threatened, endangered, or sensitive wildlife observed include the peregrine falcon and the bald eagle (United States Department of Transportation 1998). These two species are transitory near the airport.

A Level I scoping ecological risk assessment of the IRP study area was conducted on 12 and 15 September 2000. This scoping assessment was a qualitative determination of the existence of ecological receptors and/or exposure pathways at each of the ten IRP sites. The full qualitative analysis of potential ecological risks is presented in the Site Ecology Scoping Report (ERM 2001a, Appendix CC).

The results of the Level 1 scoping assessment indicated that eight of the ten IRP sites contain no ecological receptors or exposure pathways. These sites are currently covered by asphalt/concrete pavement, gravel, and/or landscaped grassland, and no aquatic habitats (i.e., storm ditches, wetlands, or streams) occur within the immediate vicinity of the sites. The remaining two sites (Sites 4 and 7) contain potential ecological receptors and exposure pathways; however, ecological risks are not suspected at these sites under current conditions due to the limited contamination and the lack of sensitive ecological receptors (i.e., threatened and endangered species and the respective habitats for either species). To verify the lack of potential impacts to ecological receptors at IRP Site 4, the ANG plans to conduct a Level II (screening) ecological risk assessment in accordance with ODEQ guidance.

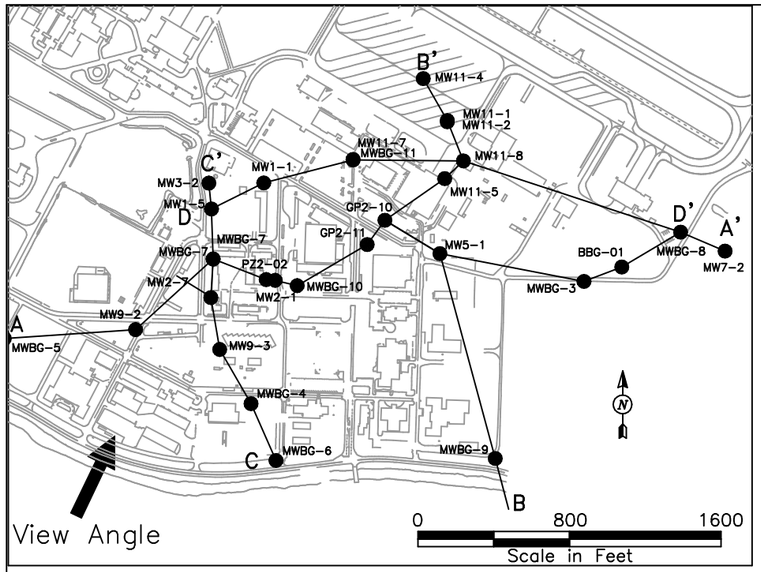
2.6 Geology

2.6.1 Regional Geology

The northeastern Portland area is underlain by Tertiary and Quaternary sedimentary and volcanic deposits. The Portland ANGB is in the central portion of the Portland Basin, a northwest-southeast trending structural depression that was formed in the early Tertiary and filled with

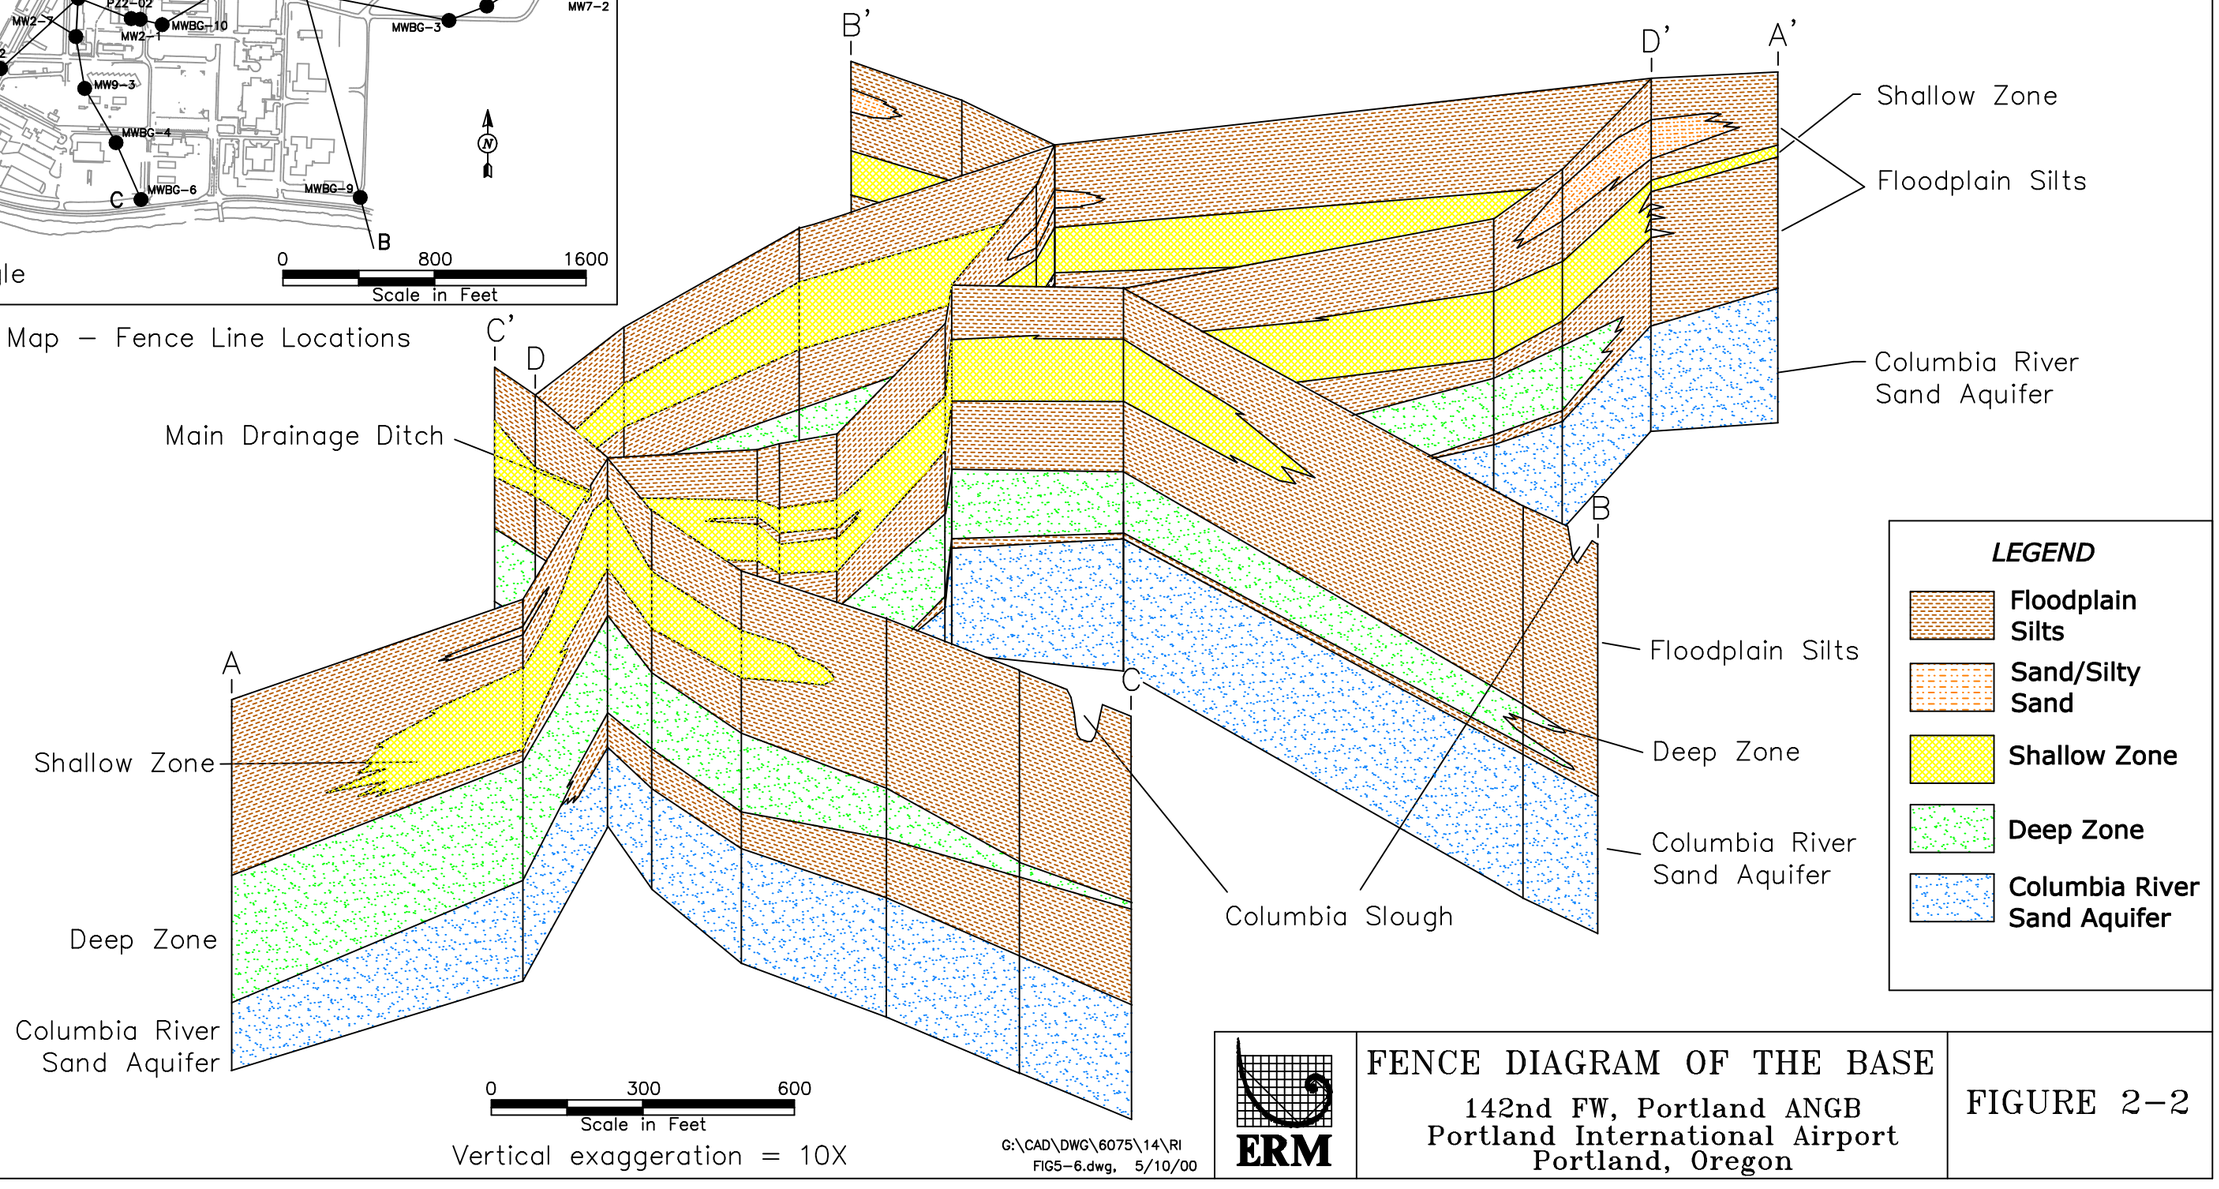
approximately 1,800 feet of late Tertiary and Quaternary sediments. In ascending order, the basin deposits in the vicinity of the Portland ANGB include Eocene and Miocene rocks, the Sandy River Mudstone, the Troutdale Formation, the Parkrose Formation, the Troutdale Gravel, the Columbia River Sand, and Pleistocene to Recent Alluvium (Hartford and McFarland 1989). The Final RI report (ERM 2001a) describes the geology of the Portland ANGB in detail.

Sediments encountered in borings drilled at the Portland ANGB include Pleistocene to Recent Alluvium and the Columbia River Sand. In the area of the Base and the Portland well field, these sediments have been divided into two distinct hydrogeologic units: the Floodplain Deposits and the Columbia River Sand Aquifer (CRSA). A fence diagram constructed from the cross sections is shown on Figure 2-2.



Most of the original surface soils at the Portland ANGB have been altered by regrading or construction activities, or have been covered by fill. Original native soils in the area include Pilchuck and Sauvie-Rafton soils. Pilchuck soils, consisting of dark, grayish-brown to dark brown soil with high permeability, underlie most of the Base. Sauvie-Rafton soils, consisting of poorly drained, silty loam soil, are present in the southeast corner of the Base. The surficial soil at the Base is approximately 15 inches thick and is underlain by a dark brown, silty loam to a depth of about 60 inches. A soils map for the Portland ANGB is included on Figure 2-3.

2.6.2 Hydrogeology



At the Portland ANGB, the Floodplain Deposits extend from the ground surface to depths ranging from approximately 48 to 60 feet below ground surface (bgs). Water-bearing zones within these Floodplain Deposits consist of, in descending order, the Upper Zone, the Shallow Zone, and the Deep Zone. A generalized hydrogeologic cross section for the Portland ANGB is shown on Figure 2-4. A conceptual hydrogeologic model for the Base and the surrounding area is presented on Figure 2-5.

2.6.2.1 Upper Zone

The Upper Zone is a discontinuous, unconfined to semi-confined water-bearing zone that is present at scattered locations in the northern, eastern, and southwestern portions of the Portland ANGB. It consists of brown, well-sorted, fine sand in the eastern portion of the Base, and silty to fine sand in the southwestern and northern portions of the Base. The Upper depths ranging from 5.5 to 9.0 feet bgs, and in thickness ranging from 1 to

Zone was encountered in several borings at IRP Sites 1, 7, 9, and 11 at approximately 18 feet. The Upper Zone is separated from the Shallow Zone by a silty low-permeability zone up to 6 feet thick, and in some areas grades directly into the Shallow Zone.

Hydraulic conductivity values are not available for the Upper Zone; however, hydraulic conductivities from 0.54 to 15 feet per day (ft/day) are estimated based on the similar grain-size distribution of the Upper Zone and Shallow Zone.

2.6.2.2 Shallow Zone

The Shallow Zone is the shallowest extensive and laterally continuous water-bearing zone at the Portland ANGB. It is a semiconfined aquifer consisting of dark gray, well-sorted, fine sand with occasional silt and scattered silty layers. The Shallow Zone was encountered in all but the southern-most borings drilled during the Site Investigation (SI) and the RI. The top of the Shallow Zone was encountered at depths of 7.5 to 21 feet bgs. Where observed, the Shallow Zone generally ranges in thickness from approximately 3 to 19 feet, and is thickest through the central portion of the Base.

The hydraulic conductivity of the Shallow Zone ranges from 0.54 to 15 ft/day based on aquifer pumping and slug tests completed during the RI. A silty low-permeability zone ranging from 2 to 14 feet thick separates the Shallow Zone from the Deep Zone.

The impacted groundwater at the Base primarily occurs within the Shallow Zone unit. The presence of the silty soils between the Shallow Zone and the Deep Zone has limited the downward migration of contaminants from the Shallow Zone, although impacts to the Deep Zone have been confirmed.

2.6.2.3 Deep Zone

The Deep Zone is an extensive, laterally continuous, and semiconfined water-bearing zone that is typically encountered below depths of 28 to 41 feet bgs and consists of gray fine sand with occasional silt and interbedded silty layers. The Deep Zone was encountered in every deep boring across the IRP study area, with the exception of the boring completed for well MWBG-8, near the eastern Base boundary. Where

observed, the Deep Zone ranges in thickness from approximately 2 to 19 feet.

The hydraulic conductivity of the Deep Zone ranges from 0.46 to 68 ft/day based on aquifer pumping and slug tests completed during the RI. In most areas of the Portland ANGB, the Deep Zone is separated from the underlying CRSA by an intervening low-permeability zone of gray clayey silt that ranges in thickness from less than 1 foot to 12 feet. In one location at the Portland ANGB (MW9-2), the Deep Zone was observed to be in contact with the CRSA. In general, the aquitard between the Deep Zone and the CRSA is thickest in the northern and northeastern portions of the IRP study area, and thinnest in the central and southwestern portions (Figure 2-2).

2.6.2.4 Columbia River Sand Aquifer

At the Portland ANGB, the CRSA is a semiconfined aquifer consisting of gray, fine-to-medium, micaceous, dense sand. The top of the CRSA was encountered at depths ranging from approximately 48 to 60 feet bgs. Logs of borings that penetrate the CRSA at the PIA note the bottom of the unit at approximately 280 feet bgs. The hydraulic conductivity of the CRSA ranges from 16 to 190 ft/day based on aquifer pumping and slug tests completed during the RI.

The Portland Well Field (Figure 1-1) has wells screened in the CRSA. The Western Expansion Area (WEA) of the Portland Well Field would put CRSA production wells within the LOF for the Portland ANGB. The LOF is discussed further in Section 2.10.1. The vertical migration from the Shallow Zone to the CRSA is a potential migration pathway for groundwater contaminants at the Base to reach human receptors.

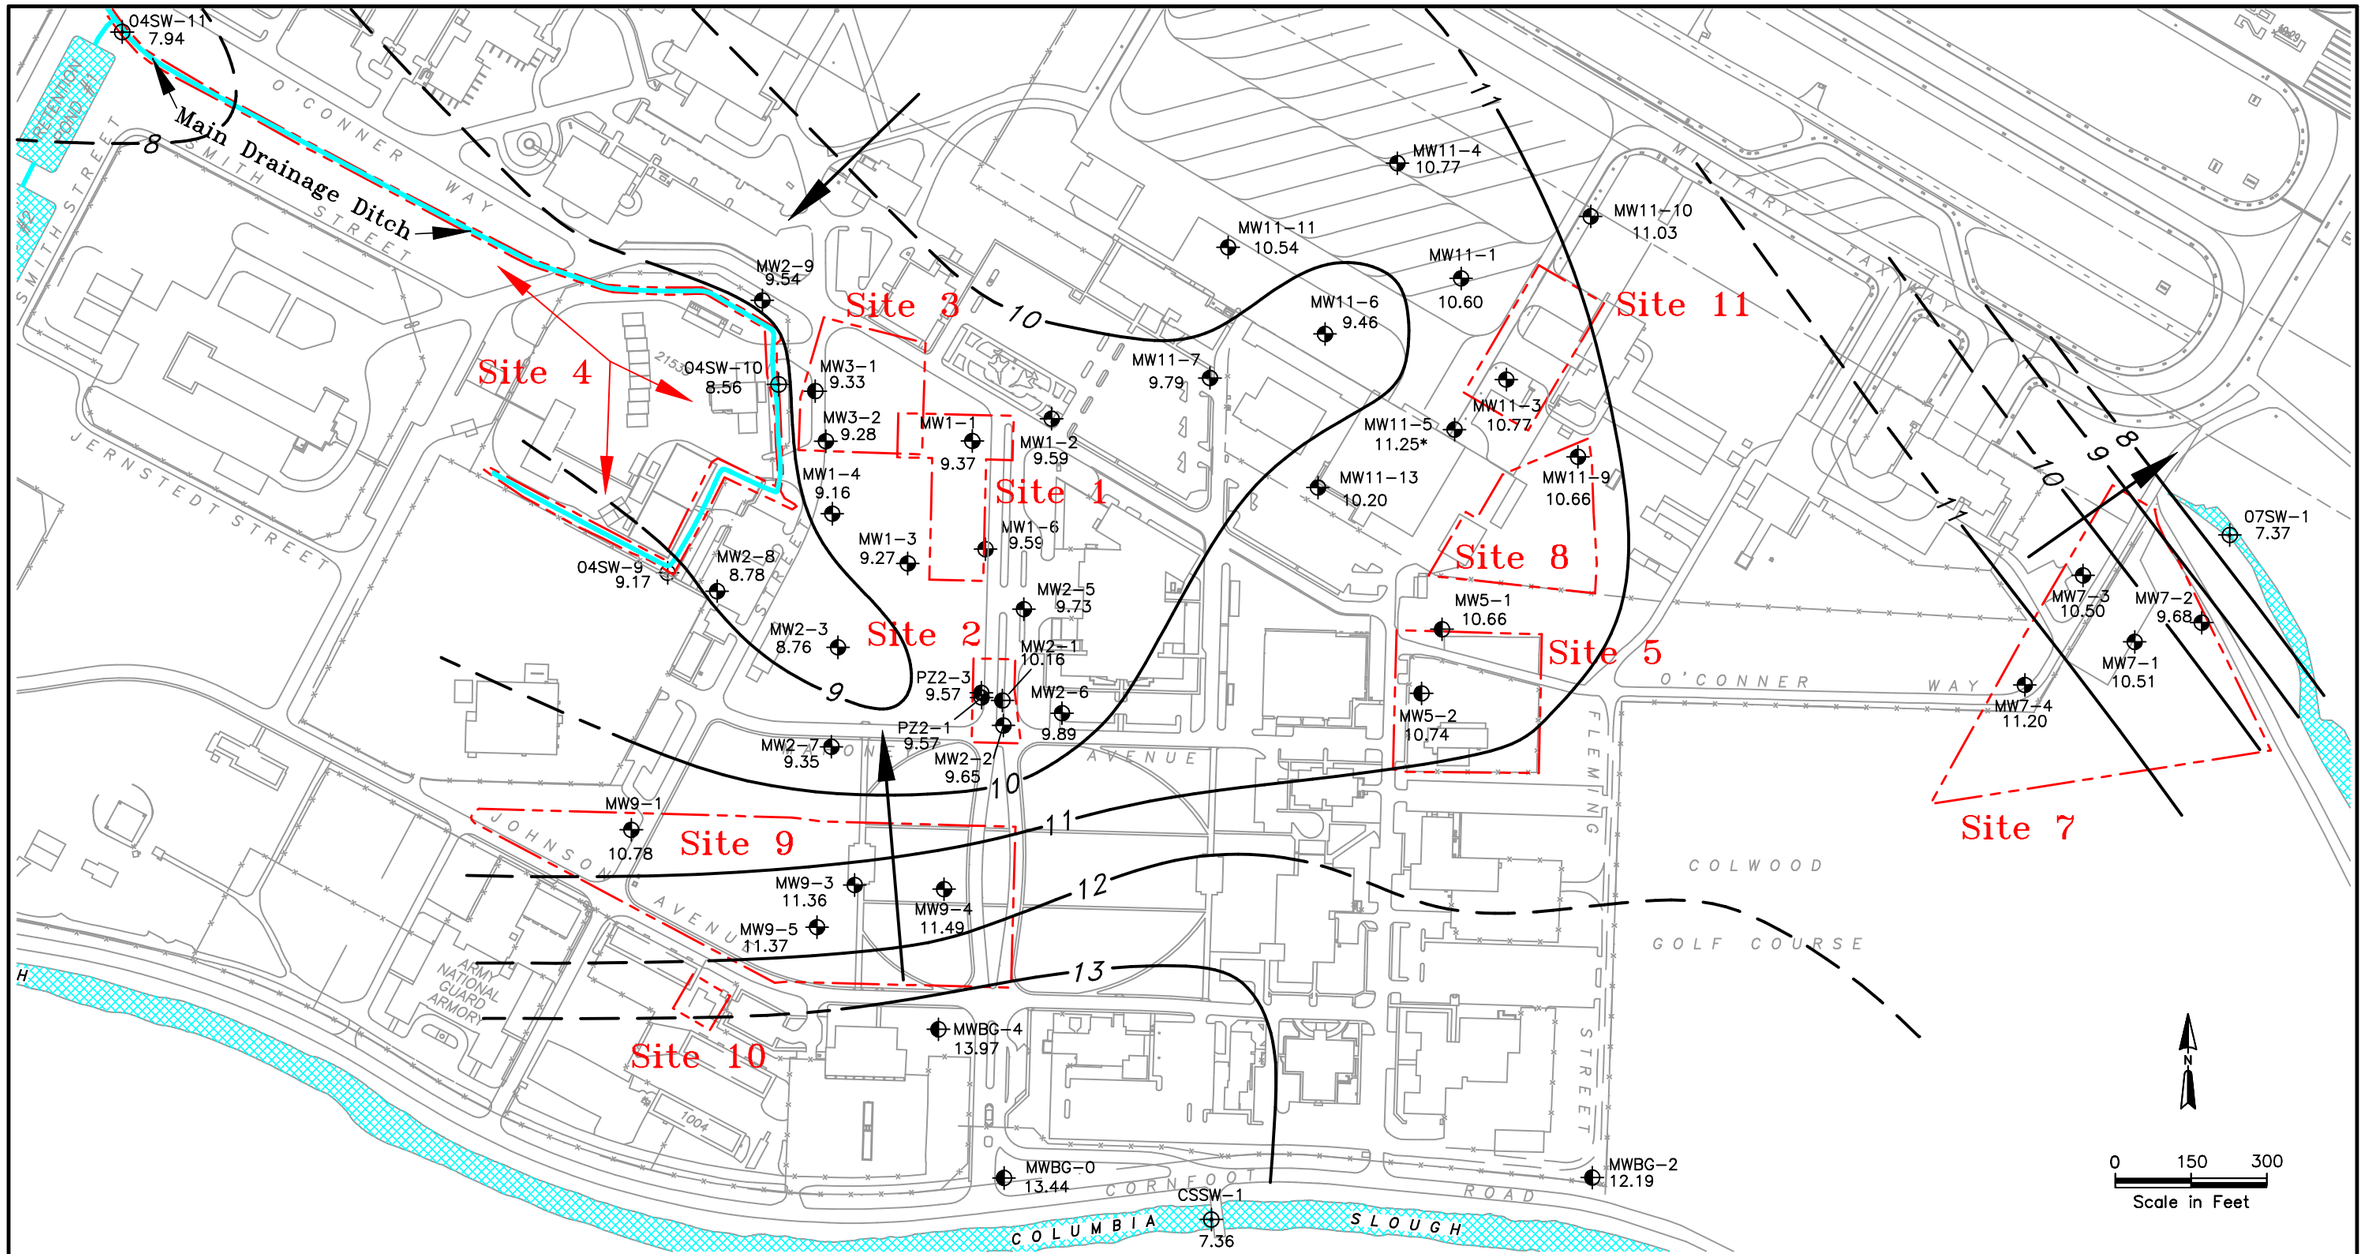
2.6.3 Groundwater Elevations

Static groundwater levels in each of the water-bearing zones at the site have been observed ranging from near the ground surface to greater than 12 feet bgs. Seasonal groundwater elevation variations of approximately 4 feet or less have been observed in each of the Shallow Zone and Deep Zone, and variations of up to nearly 6 feet have been observed in the CRSA. Continuous water level data were recorded during the RI indicate that groundwater elevations at the Portland ANGB correlate with both precipitation and Columbia River stage. The groundwater elevation in the Shallow Zone appears to correlate more closely with individual

precipitation events; whereas groundwater elevations in the Deep Zone and the CRSA correlate more closely with the Columbia River stage.

2.6.4 Groundwater Flow Directions

A potentiometric surface map for Shallow Zone water levels measured in July 2000 is presented on Figure 2-6. The inferred groundwater flow direction in the Shallow Zone in July 2000 was generally toward the northwest, converging toward the Main Drainage Ditch. However, the inferred groundwater flow direction at the eastern end of the Base (at IRP Site 7) was toward the northeast.



A potentiometric surface map for Deep Zone water levels measured in July 2000 is presented on Figure 2-7. The inferred groundwater flow direction in July 2000 was generally toward the northeast. Previous groundwater flow directions in the Deep Zone have generally been toward the north, although the cumulative water level data indicate occasional temporal and spatial shifts in groundwater flow.

The variable groundwater flow directions in the Deep Zone appear to be related to flow reversals in the CRSA. Significant changes in flow direction in both zones appear to correlate with seasonal fluctuations in the Columbia River stage. When the river stage is low, groundwater generally flows in an easterly direction in the Deep Zone. During moderate-to-high river stages, however, Deep Zone groundwater generally flows west.

The July 2000 potentiometric surface map for the CRSA is presented on Figure 2-8. The inferred groundwater flow direction in the CRSA in July 2000 was toward the northeast. Groundwater flow in the CRSA during previous quarters has fluctuated between northerly and southerly directions. Groundwater flow directions in the CRSA appear to be largely controlled by the Columbia River stage.

2.6.5 Hydraulic Gradients

In July 2000, the horizontal hydraulic gradients in the Shallow Zone and Deep Zone varied across the IRP study area, but averaged approximately 0.004 feet per foot in the Shallow Zone and 0.001 feet per foot in the Deep Zone. The average horizontal hydraulic gradient in the CRSA in July 2000 was approximately 0.0003 feet per foot. Horizontal gradients observed during previous quarters were similar in magnitude to the July 2000 gradients.

FIGURE 2-8

In July 2000, the vertical gradient was downward at eight Shallow Zone/Deep Zone well pair locations and upward at one location. The vertical gradient was downward at each of the three Deep Zone/CRSA well pair locations. Gradient magnitudes ranged from 0.002 feet per foot to 0.752 feet per foot. The variable vertical gradients observed in July 2000 and previous months reflect lateral variations in both the horizontal hydraulic gradients within the water-bearing zones and the thickness of the silt layers between the zones.

2.7 Previous Investigations and Remedial Actions

Beginning in 1987, four IRP investigation phases have been completed at the Portland ANGB: the PA, the SI, the RI, and the Engineering Evaluation/Cost Analysis (EE/CA) Investigation. In addition, quarterly groundwater monitoring has been conducted since January 1997. These investigations are summarized in the following subsections.

2.7.1 Preliminary Assessment

In 1987, under the United States Air Force IRP as implemented by the ANG, a Phase I Record Search was completed and recorded as part of the PA (HMTC 1987). The PA investigation included: an on-site visit to interview past and present Portland ANGB employees; the acquisition and analysis of pertinent information and records on the Portland ANGB's hazardous materials use and waste generation and disposal practices; and the analysis of available geological, hydrological, meteorological, and environmental data from Federal, State, and local agencies.

The PA evaluated eight sites on the Portland ANGB (IRP Sites Nos. 1 through 8), and ranked six of these sites in accordance with the United States Air Force Hazardous Assessment Rating Methodology Protocol. The eight sites evaluated during the PA are as follows:

- IRP Site 1 - Central Hazardous Waste Storage Area
- IRP Site 2 - Civil Engineering Hazardous Material Storage Area
- IRP Site 3 - Hush House Area
- IRP Site 4 - Main Drainage Ditch
- IRP Site 5 - Aerospace Ground Equipment (AGE) Maintenance Shop

- IRP Site 6 - Wash Rack West of Building 1355
- IRP Site 7 - Burn Pit Area
- IRP Site 8 - Sanitary Landfill

Following the PA, limited field sampling was conducted at IRP Site 4 by RN Smith Associates in 1987, and at IRP Site 3 by SRH Associates, Inc., in 1988 (SRH 1988).

In December 1988, the Oregon ANG reported an underground storage tank (UST) leak at the POL Facility to the ODEQ. The fuel leak resulted in the identification of an additional IRP site, IRP Site 9 - POL Facility.

2.7.2 Site Investigation

In 1989, an SI of the IRP sites identified in the PA as requiring further investigation (IRP Sites 1 through 5, 7 and 8) was implemented by SAIC. The results of the SI are reported in the *Site Investigation Report* (SAIC 1991).

During the SI phase of work, two additional IRP sites were identified, based on the previous analytical results from samples collected by Portland ANGB personnel:

- IRP Site 10 - Equipment Wash Rack
- IRP Site 11 - Wash Rack West of Building 250 (Formerly IRP Site 6)

2.7.3 Remedial Investigation

Between 1995 and 2000, a multi-phase RI was performed at the Portland ANGB. The RI included the following phases:

- A Phase I RI performed by Operational Technologies Corporation (OpTech 1996);
- A Remedial Investigation/Data Gap Evaluation (RI/DGE) performed by ERM (ERM 1997); and
- An RI performed by ERM (ERM 2001a).

Descriptions of each of the above-referenced phases is provided in the following subsections.

2.7.3.1 Phase I RI

In 1995 and 1996, a Phase I RI was performed by OpTech. The field activities performed during the Phase I RI consisted of installing monitoring wells; collecting soil, sediment, soil gas, and groundwater samples; conducting aquifer tests; and performing geophysical surveys at ten of the IRP sites. The results of the Phase I RI were documented in the *Draft Remedial Investigation Report* (OpTech 1996).

2.7.3.2 Remedial Investigation/Data Gap Evaluation

In 1997, ERM conducted an RI/DGE to fill data gaps in the SI and Phase I RI. RI/DGE activities were performed at IRP Sites 1, 2, 5, 7, and 11. The results of the RI/DGE were presented in the *Final Investigation/Data Gap Evaluation (RI/DGE) Technical Memorandum* (ERM 1997).

2.7.3.3 Phase II RI

Phase II RI field activities were performed by ERM from April 1998 through November 1999 at IRP Sites 1, 2, 3, 4, 5, 7, 9, 10, and 11. The Phase II RI consisted of the following screening and confirmation activities, and additional supporting tasks:

Screening Activities

- Organic vapor (headspace) screening of soil samples; and
- Direct-push groundwater sampling to assess the nature and extent of contamination in groundwater and identify possible source areas.

Confirmation Activities

- Sediment and surface water sampling to determine the nature and extent of contamination in the Main Drainage Ditch;
- Surface and subsurface soil sampling to determine the nature and extent of contamination in soil; identify possible source areas for groundwater contamination; and determine lithology; and
- Installation and sampling of groundwater monitoring wells to determine the nature and extent of contamination in groundwater and monitor potential contaminant migration.

Supporting Tasks

- Measuring groundwater and surface water elevations to characterize hydraulic gradients, groundwater flow patterns, and groundwater/surface water interactions;
- Conducting aquifer testing to determine aquifer hydraulic properties;
- Performing a natural attenuation evaluation to assess the occurrence and rate of dissolved contaminant losses from groundwater due to intrinsic natural processes (for example, biodegradation);
- Conducting groundwater flow modeling to predict the effects of possible, future groundwater withdrawal in the Portland well field WEA;
- Performing an in-well aerator pilot test to assess the efficacy of this remediation technology for reducing chlorinated volatile organic compound (VOC) concentrations in groundwater;
- Conducting location and elevation surveys of the Phase II RI soil borings, groundwater sampling/monitoring points, and surface water measurement benchmarks; and
- Performing a baseline risk assessment to evaluate the potential human health and ecological risks associated with contaminated soil, sediment, groundwater, and surface water.

Soil and/or groundwater samples were collected from direct-push borings, hand-auger borings, hollow-stem auger borings, groundwater monitoring wells, groundwater extraction wells, and piezometers. The results of the Phase II RI are presented in the Final RI Report (ERM 2001a).

2.7.4 EE/CA Investigation and Removal Action

During January through March 1998, ERM performed an EE/CA Investigation at IRP Site 11 to define the lateral and vertical extent of chlorinated- and hydrocarbon-impacted soil at the site. The scope of work of the EE/CA Investigation included the installation of 24 direct-push soil borings, and the collection of a groundwater sample at each location. The results of the EE/CA Investigation were reported in the *Final Engineering Evaluation/Cost Analysis (EE/CA) for IRP Site 11*, (ERM 1998).

A soil removal action was performed at the site in September 1999 as part of the soil EE/CA process. The following scope of work was completed as part of this removal action:

- Sludge and water were removed from the oil/water separator;
- The oil/water separator and washrack were removed and hauled off-site; and
- Approximately 260 cubic yards of impacted soil were removed in the immediate vicinity of the former oil/water separator and hauled off-site to a thermal desorption facility.

The scope results of the 1999 soil removal action are detailed in the *Final Completion Report for Site 11 Interim Remedial Action Construction for Soils Media*, (ERM 2000b).

2.8 Current IRP Activities

Current IRP environmental activity at Portland ANGB includes an EE/CA for a non-time critical, groundwater removal action at IRP Site 11, an IRAC project to evaluate groundwater remediation technologies at IRP Site 2, and ongoing groundwater monitoring. These activities are described in the following subsections.

2.8.1 IRP Site 11 Groundwater EE/CA

A general description of how the EE/CA fits into the FS process is presented in Appendix A. The EE/CA currently being conducted at IRP Site 11 closely parallels this FS, in that many components are similar, such as the establishment of RAOs, the development of remedial alternatives, the detailed analysis of such alternatives, and the selection of a preferred RA alternative. The EE/CA Report follows the recommended ANG/CEVR format and contains the information suggested in the USEPA document *Guidance on Conducting Non-Time-Critical Removal Actions Under CERCLA* (USEPA 1993). The *Final Site 11 Groundwater EE/CA* was submitted in June 2001 (ERM 2001b). In addition, a conceptual design document, representing the first phase of design of the remedial action recommended in the EE/CA, was submitted in April 2001.

2.8.2 IRP Site 2 Interim Remedial Action Construction

The other IRP work currently being conducted at the Portland ANGB is a two-phase, IRAC for the purposes of providing treatability testing support for the FS, and to begin cleanup of groundwater at IRP Site 2. The results of the IRAC will be used to evaluate treatment of VOCs in groundwater across the Base.

The first phase of the IRAC involved a three-month treatability test to evaluate the effectiveness of three in-situ remediation technologies for treatment of VOCs in groundwater at IRP Site 2: enhanced aerobic bioremediation with Oxygen Release Compound (ORC®), ozonation, and potassium permanganate oxidation.

The treatability test phase of the IRAC has been completed. The results indicate that all three technologies were effective in destroying VOCs in groundwater. Certain site-specific factors such as preferential flow paths, high levels of organic carbon in the soil, and low horizontal hydraulic gradient appear to present limitations to treatment at the site. A summary of the IRAC treatability results are presented in the *Interim Remedial Action Construction Phase I Interim Report* submitted in February 2001 (ERM 2001c). A work plan for the second phase of the IRAC has been prepared and the full-scale technology demonstration is expected to be implemented in fall of 2001 (ERM 2001d).

The second phase of the IRP Site 2 IRAC will involve the full-scale demonstration of in situ oxidation by potassium permanganate injection. The purpose of this phase will be to demonstrate that the preferred remediation technology is effective, on a larger scale, at reducing human health and environmental risk to an appropriate level.

2.8.3 Groundwater Monitoring

Basewide groundwater monitoring at the Portland ANGB is expected to continue. Future groundwater monitoring will focus on potential off-site contaminant migration and/or downward migration to the CRSA drinking water aquifer at Sites 2, 9, and 11.

2.9 Contaminant Fate and Transport

This section presents some of the results of the contaminant fate and transport analysis performed during the RI. A more complete discussion of contaminant fate and transport is presented in the Final RI Report (ERM 2001a).

Release mechanisms for contaminants of concern (COCs) in soil include infiltration of precipitation and direct contact of the water table with contaminated soil. The primary pathways for contaminant migration at the Portland ANGB are:

- Leaching of soil contaminants to groundwater; and
- Transport of contaminants away from source areas via advection and dispersion in groundwater.

2.9.1 Leaching of Soil Contaminants

Precipitation has the potential to infiltrate and contact contaminated soil at IRP Sites 1, 3, 5, 7, 9, 10, and 11; however, leaching of the relatively immobile metals detected in surface soil at Sites 5 and 10 is likely insignificant. The rate of contaminant migration for this pathway is controlled by the infiltration rate of precipitation, the contact time between the infiltrating water and the contaminants, the rate of evaporation, the permeability and wetting characteristics of the soil, and the solubility of the COCs. The precipitation infiltration rate in turn depends on seasonal precipitation rates and ground surface conditions (e.g., paved / unpaved, surface vegetation, slope).

2.9.2 Groundwater Transport

Groundwater contamination is present at IRP Sites 1, 2, 3, 9, and 11. Groundwater typically occurs between 2 and 10 feet bgs in monitoring wells at the Portland ANGB. Horizontal groundwater flow occurs primarily through the permeable sand zones. From the surface, infiltrating precipitation contacts the water table within the Floodplain Silt and flows downward to the Shallow Zone. Groundwater then flows horizontally through the Shallow Zone. In areas where the groundwater elevation in the Deep Zone is less than the groundwater elevation in the Shallow Zone, groundwater can potentially flow downward to the Deep

Zone. Likewise, in areas where the groundwater elevation in the CRSA is less than that in the Deep Zone, groundwater can potentially flow downward to the CRSA. Downward vertical hydraulic gradients were observed at various times and locations during the Phase II RI and Basewide groundwater monitoring program.

The results of aquifer testing indicate that vertical groundwater flow through the silt layer separating the Shallow and Deep Zones is relatively slow. The vertical hydraulic conductivity of this silt layer is estimated to be approximately 1.9 gpd/ft^2 (0.25 ft/d) based on pumping test data. Assuming an effective porosity of 30 percent and a vertical hydraulic gradient of 0.001 feet per foot (consistent with observed gradients at IRP Sites 1, 2, and 3) the groundwater seepage velocity through the silt layer is estimated to be on the order of 0.001 ft/d. The seepage velocity through the silt layer separating the Deep Zone from the CRSA is expected to be similar in magnitude.

2.9.3 Groundwater Flow Modeling Results

A groundwater flow model was developed to predict the effects of potential future groundwater withdrawal in the Portland well field WEA on the groundwater flow regime under the Portland ANGB. The WEA is approximately 1.5 miles east of the Base.

The numerical groundwater model was constructed using Visual MODFLOW, a widely used groundwater modeling software package. The basis for the Portland ANGB groundwater model is the City of Portland's Deep Aquifer Yield flow model, which was developed to evaluate groundwater response to pumping in the Portland well field.

The Portland ANGB model was used to conduct predictive simulations of several different pumping scenarios in the Portland well field. In one of the scenarios, the two existing CRSA/Troutdale Gravel Aquifer (TGA) production wells in the WEA and a third CRSA well approximately 3,000 feet east of the WEA were assumed to pump continuously at maximum capacity (3,000 to 6,000 gallons per minute per well). The modeling results for this scenario predict that the pumping wells would not induce groundwater under the Portland ANGB to flow toward the Portland well field.

Another pumping scenario under consideration by the City of Portland involves the installation and operation of two new TGA production wells in the WEA, in addition to the existing TGA well. The modeling results

predict that this pumping configuration would cause groundwater under the Base to migrate toward the pumping wells. However, after 3 years of continuous pumping (the maximum anticipated duration of pumping under this scenario), Shallow Zone groundwater would migrate primarily west and then downward into the Deep Zone; lateral migration toward the Portland well field is predicted to be on the order of 100 feet or less. The results for this scenario suggest that the production wells would have to be pumped continuously at full capacity for approximately 26 years before Shallow Zone groundwater under the Base would reach the closest production well.

A third pumping scenario was modeled to evaluate whether any of the new CRSA/TGA production wells currently proposed by the City for the WEA could be installed and operated along with the existing shallow production wells, without significantly affecting groundwater flow under the Portland ANGB. The results for this scenario suggest that up to two additional shallow production wells could be installed at proposed well sites in the WEA. These new wells and the three existing wells could be pumped continuously at capacity with minimal impact on groundwater flow under the Base.

The predictive simulations in the present modeling study are a first-order approximation of the expected groundwater flow response to the pumping scenarios evaluated. A number of simplifying assumptions were made in developing the model, and the inputs to the model were based on limited field data. Additionally, the model simulations assumed steady-state conditions and a static water level in the Columbia River. Water level data for the Portland ANGB and the Columbia River, as well as the observed model behavior during calibration and sensitivity analysis, indicate that the groundwater flow system is very dynamic.

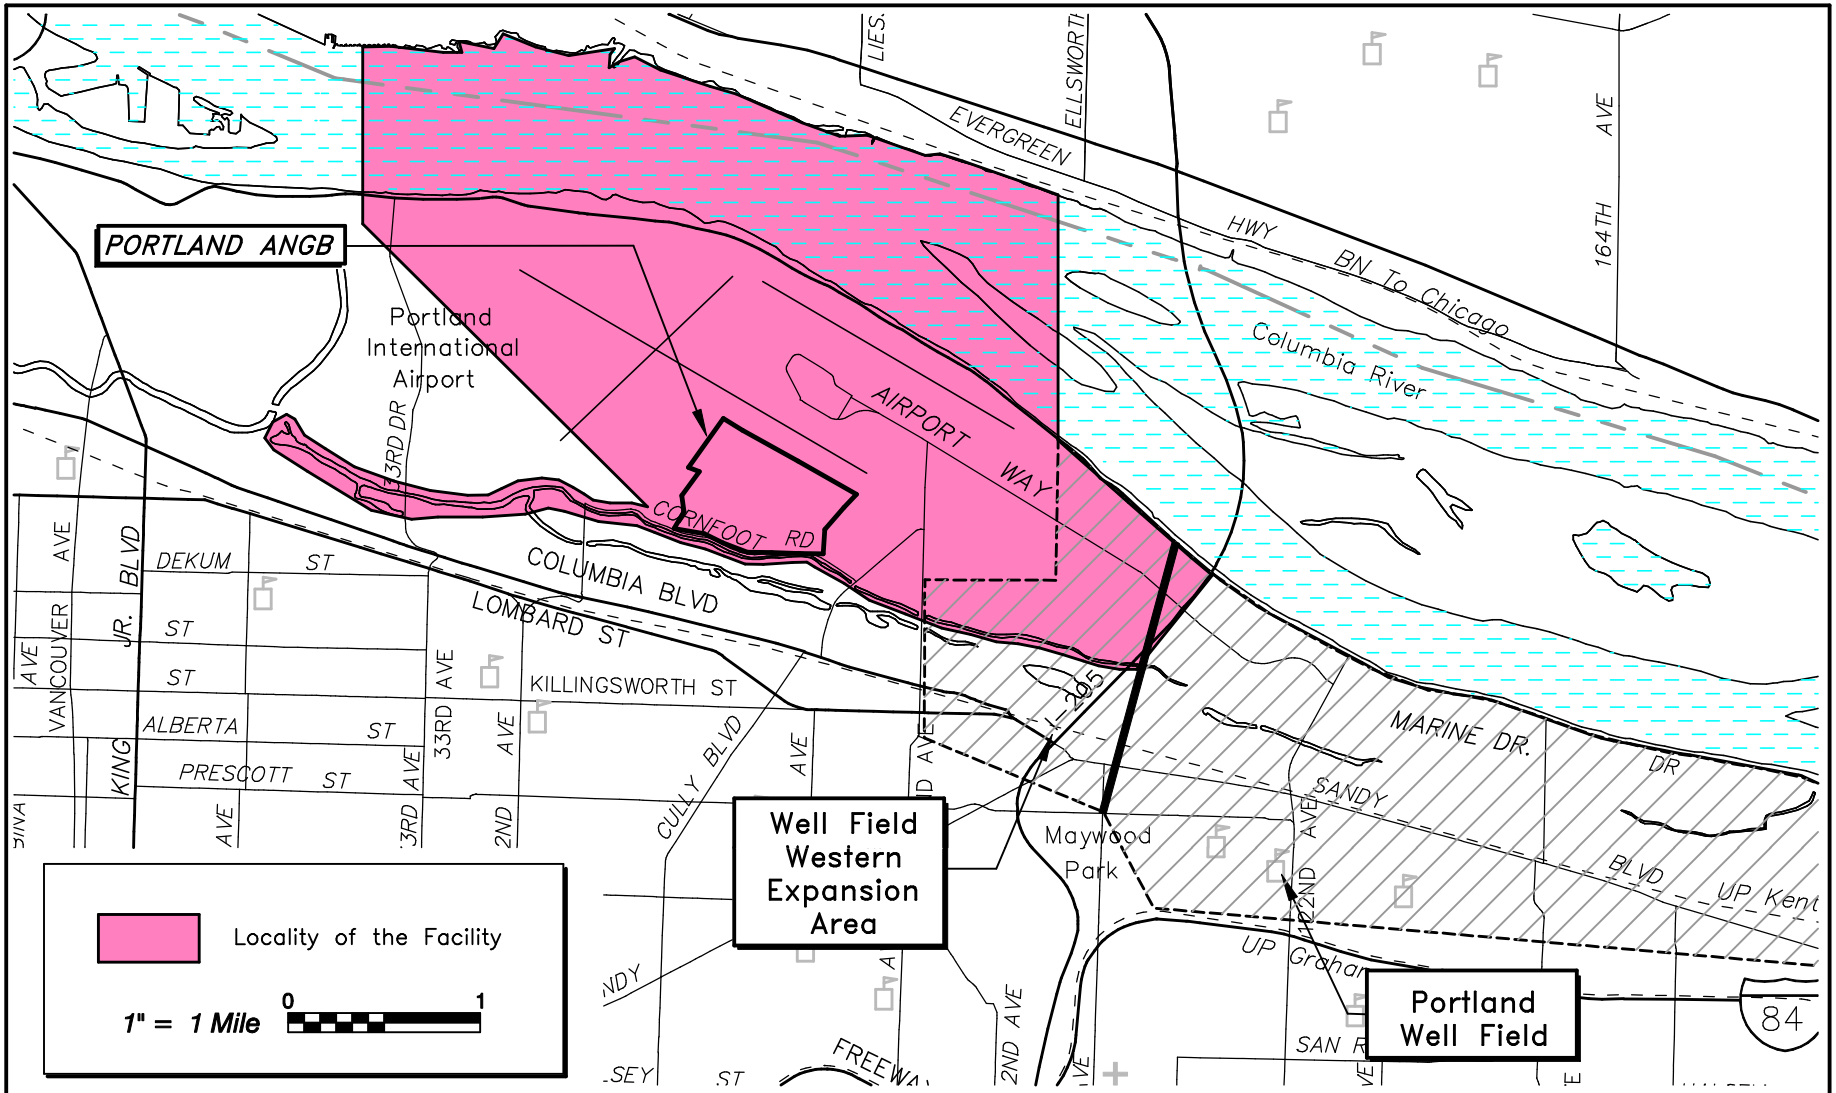
Further discussion regarding groundwater transport and modeling is presented in the Final RI document, including further discussion of uncertainties associated with the groundwater flow monitoring. Also, contaminant transport modeling is currently being performed for the Base and these results will be documented late in 2001.

2.10 Beneficial Use Survey

This section summarizes the results of the beneficial use survey completed for the Portland ANGB.

2.10.1 Locality of the Facility

Oregon regulations require the identification of current and reasonably likely future beneficial water uses in the LOF. LOF is defined in Oregon Administrative Rules (OAR) 340-122-115(34) as any point where a human or an ecological receptor contacts, or is reasonably likely to come into contact with, facility-related hazardous substances. The LOF takes into account the likelihood of the contamination migrating over time, and as such is typically larger than the facility (ODEQ 1998a).



Based on modeling and migration scenarios developed in the Final RI Report (ERM 2001a), the LOF for the Base was determined to extend a significant distance beyond the actual Base footprint. The LOF for the Base, as shown on Figure 2-9, includes off-site areas such as a portion of the Columbia River, the Columbia Slough, and the Portland Well Field. The extent of the LOF for the Base was established based on the slight potential for existing VOCs in groundwater at IRP Sites 2, 9, and 11 to migrate to the above-mentioned areas.

2.10.2 Groundwater

Groundwater within the property boundary of the Portland ANGB is not currently used and there is no plan to use Base groundwater in the future. The industrial nature of the current and planned future use of the Base limits the potential for installing production wells. However, the groundwater resources at the Base, particularly the CRSA, have the capacity to sustain production for uses other than municipal supply, such as use on-site for process water, wash water, or on-site drinking water.

The off-site portion of the LOF includes part of the Portland well field, the Columbia River, and the Columbia Slough. The only current beneficial use of groundwater for this area is recharge of surface water. There are currently no groundwater production wells within the LOF (ERM 2001a). However, the LOF includes the Portland well field WEA, where future pumping of CRSA groundwater could occur.

Possible future beneficial uses of groundwater at the LOF include uses typical of a municipal water supply (drinking, irrigation, industry, etc.) and recharge of surface water. It is possible that planned wells within the Portland well field WEA will be activated. If these wells were activated, there is a potential, under certain pumping scenarios, that groundwater containing VOCs from IRP Sites 2, 9, or 11 could reach the well field.

PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 2-9

There is also slight potential for groundwater containing VOCs to migrate directly or indirectly to the surface water resources mentioned above. This could effect beneficial uses of these resources, depending on the concentration of VOCs reaching the surface water body. The beneficial use of surface water is discussed in the section below.

2.10.3 Surface Water

As mentioned above, three surface water bodies exist within the LOF for the Portland ANGB; (1) the drainage ditch at IRP Site 4, (2) the Columbia Slough south of the Base, and (3) the Columbia River at the northern boundary of the LOF. Beneficial use of these surface water bodies includes aquatic life habitat, recreation, aesthetic quality, and irrigation. The off-site surface water bodies are included in the LOF due to a potential hydraulic connection to the Shallow Zone at the Base.

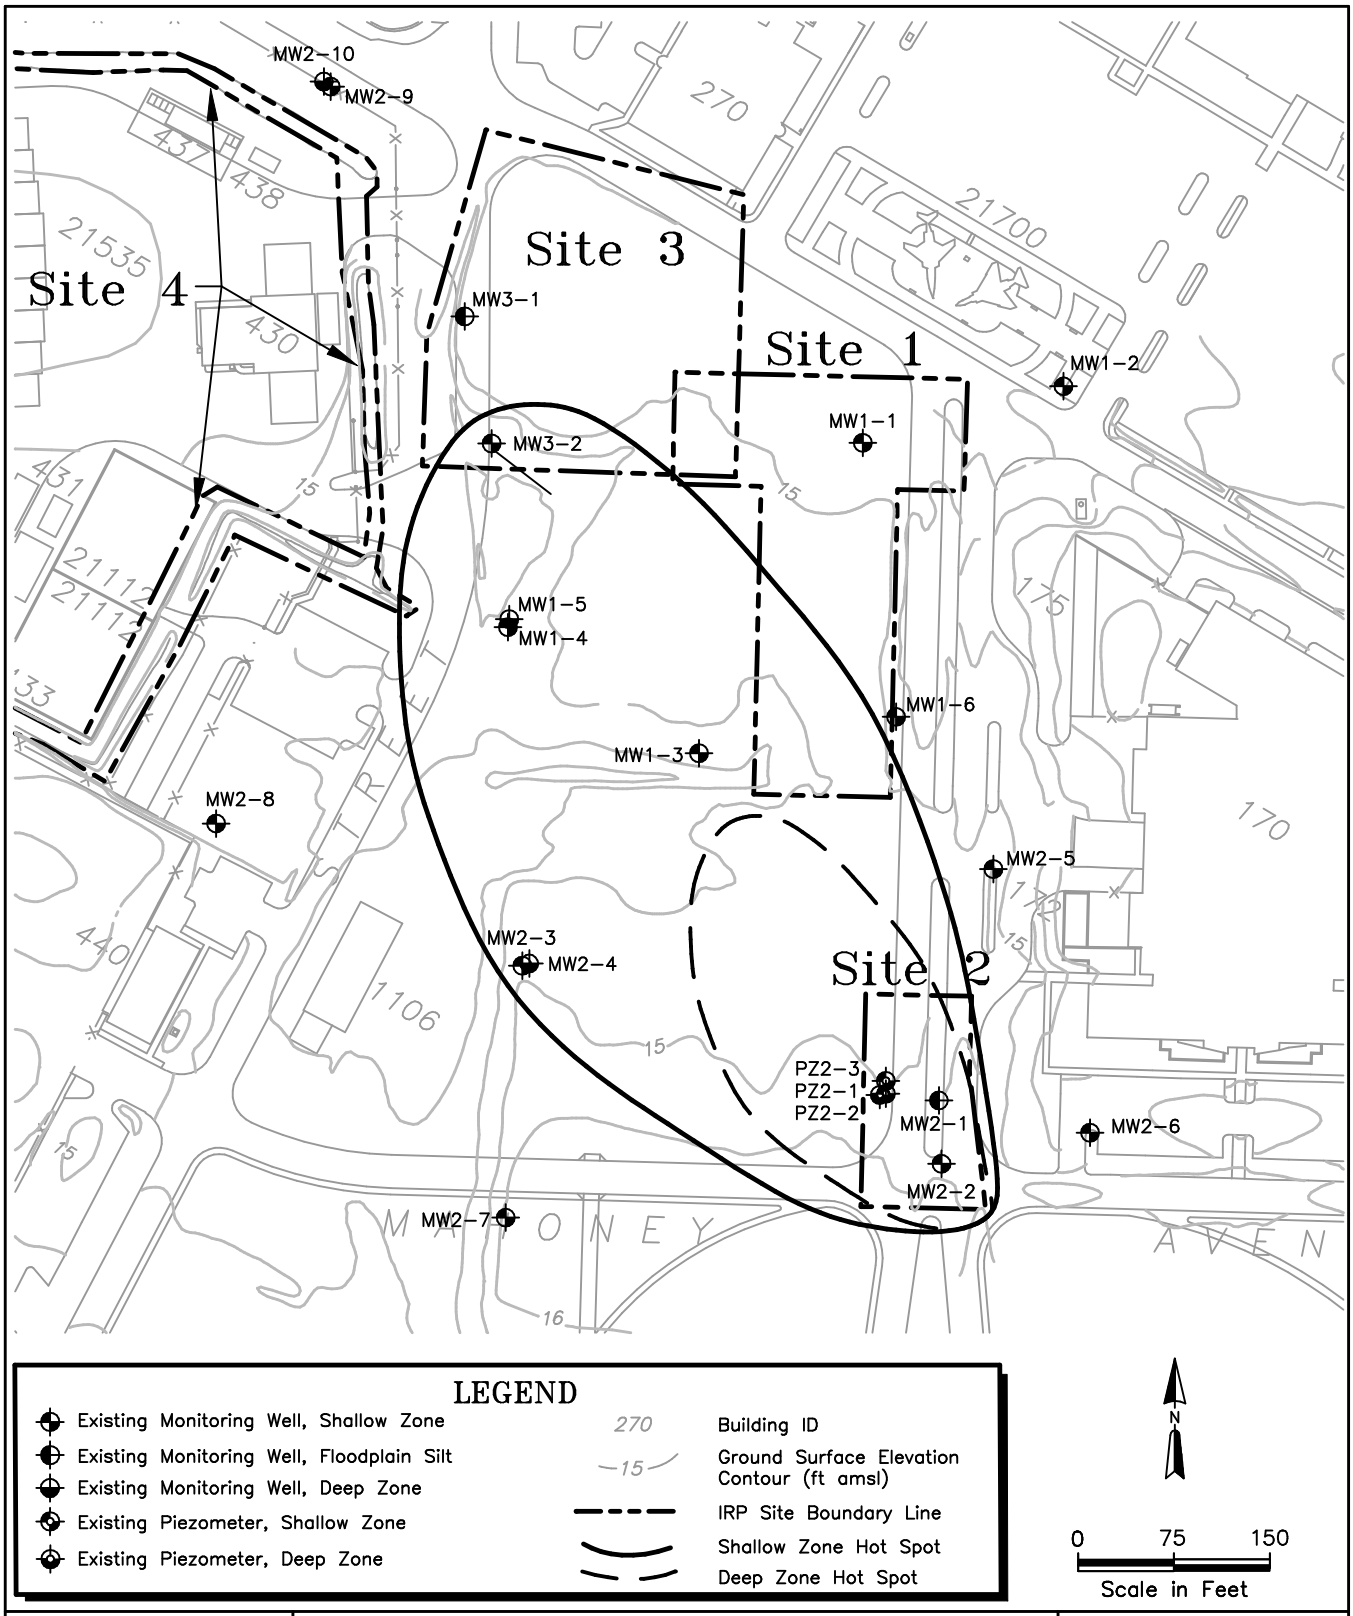
Groundwater containing VOCs at IRP Sites 2, 9, and 11 has not impacted off-site surface water. However, if left untreated, VOCs at these sites may migrate to the three above-referenced surface water bodies. The impact to the beneficial uses of the surface water is not expected to be significant due to the time and distance required for VOCs to travel from each IRP site to the nearest off-site surface water body.

2.10.4 Land Use

The Portland ANGB property is leased by the ANG from the Port of Portland. This property is zoned for industrial use (City of Portland Bureau of Planning 2000a). Current operations at the Base are consistent with this land use designation. In order to determine the likely future land use of the property, the Port of Portland planning department was contacted. In addition, the PIA Master Plan and the City of Portland Comprehensive Plan Map were reviewed.

According to the Port of Portland planning department, the Portland ANGB property is expected to be used indefinitely for aviation purposes. There is no likelihood that the Base property would eventually be developed for residential use (Port of Portland 2001). The Portland Airport Master Plan indicates that future development of the airport facilities will most likely include relocation of the Portland ANGB to an area in the northwest part of the airfield. The recommended development alternative calls for construction of a second passenger terminal and a possible third runway in the area currently occupied by the Base (Port of

Portland 2000). The City's Comprehensive Plan Map identifies the area encompassing the Portland ANGB as "Industrial Sanctuary" (City of Portland Bureau of Planning 2000b). Accordingly, the current industrial land use of the Portland ANGB property is not expected to change in the future.



2.11 Hot-Spot Evaluation

ODEQ requires that all remedies considered in an FS address treatment of "hot spots." According to the *Final Guidance for Identification of Hot Spots* (ODEQ 1998c), a hot spot exists if contamination results in a significant adverse effect on the beneficial use of that resource and if restoration or protection of the beneficial use can occur within a reasonable amount of time.

Although unlikely, future pumping scenarios in the Portland well field as described in Section 2.9 above, groundwater at the Portland ANGB has the potential to reach the WEA. The National Primary Drinking Water Standard Maximum Contaminant Level (MCL) is the criteria used to determine if a significant adverse effect exists regarding the use of groundwater at the WEA as drinking water (ODEQ 1998c). Comparing analytical data for several VOCs at IRP Sites 2, 9, and 11 with the respective MCLs indicates that a significant adverse effect would exist if groundwater from these sites were to migrate to the WEA.

The focus of this FS was to determine how to treat groundwater at IRP Sites 2, 9, and 11 to the extent necessary to prevent significant adverse effect on off-site groundwater. Remedial alternatives were developed which are expected to restore the groundwater within a reasonable timeframe.

Certain areas of groundwater at IRP Sites 2, 9, and 11 are considered hot spots based on the two principles described above. The groundwater hot spot at IRP Site 2 consists of the largest area containing an exceedence of either vinyl chloride (VC) at 2 micrograms per liter (µg/l); trichloroethene (TCE) at 5 µg/l; cis-1,2-DCE at 70 µg/l; or trans-1,2-DCE at 100 µg/l. The area of the hot spot at IRP Site 2 is delineated on Figure 2-10. The groundwater hot spot at IRP Site 9 is the area where the benzene concentration exceeds 5 µg/l. The area of the hot spot at IRP Site 9 is delineated on Figure 2-11. The groundwater hot spot at IRP Site 11 is the area where either VC exceeds 2 µg/l; cis-1,2-DCE exceeds 70 µg/l; trans-1,2-DCE exceeds 100 µg/l; or benzene exceeds 5 µg/l. The area of the hot

SECTION 3.0

IRP SITE DESCRIPTIONS

This section includes background and historical information regarding each IRP site at the Base, as well as the respective results of the RI. Subsequent to the background and historical summaries provided for each site, the information described below will be presented:

- Waste Storage/Disposal History: A brief history of the waste storage/disposal practices conducted at each IRP site is provided.

- Nature and Extent of Contamination: A summary of the contaminants identified at the site; their concentrations and spatial distribution in soil, groundwater, sediment, and/or surface water; and their exceedances of the project screening goals (PSGs) developed during the RI are presented in Table 3-1.

- Risk Assessment Results: The results of a baseline risk assessment for each IRP site are discussed. These results were the basis for the development of remedial alternatives. The development of remedial alternatives is recommended for sites with risks that exceed ODEQ and/or USEPA acceptable levels.

- Recommendations: A discussion is presented regarding what action should be taken at each IRP site, based on the level of contamination or risk. In cases where a recommendation is made for further analysis of an IRP site, remedial alternatives are fully evaluated in sections 4.0 and 5.0.

A summary of the waste disposal history, nature and extent of contamination, risk assessment results, and recommendations for each IRP site is provided in Table 3-2.

3.1 IRP Site 1 - Central Hazardous Waste Storage Area

The former Central Hazardous Waste Storage Area is on the north side of former Building 1131, as shown on Figure 3-1. The waste storage area did not have a containment structure (SAIC 1991).

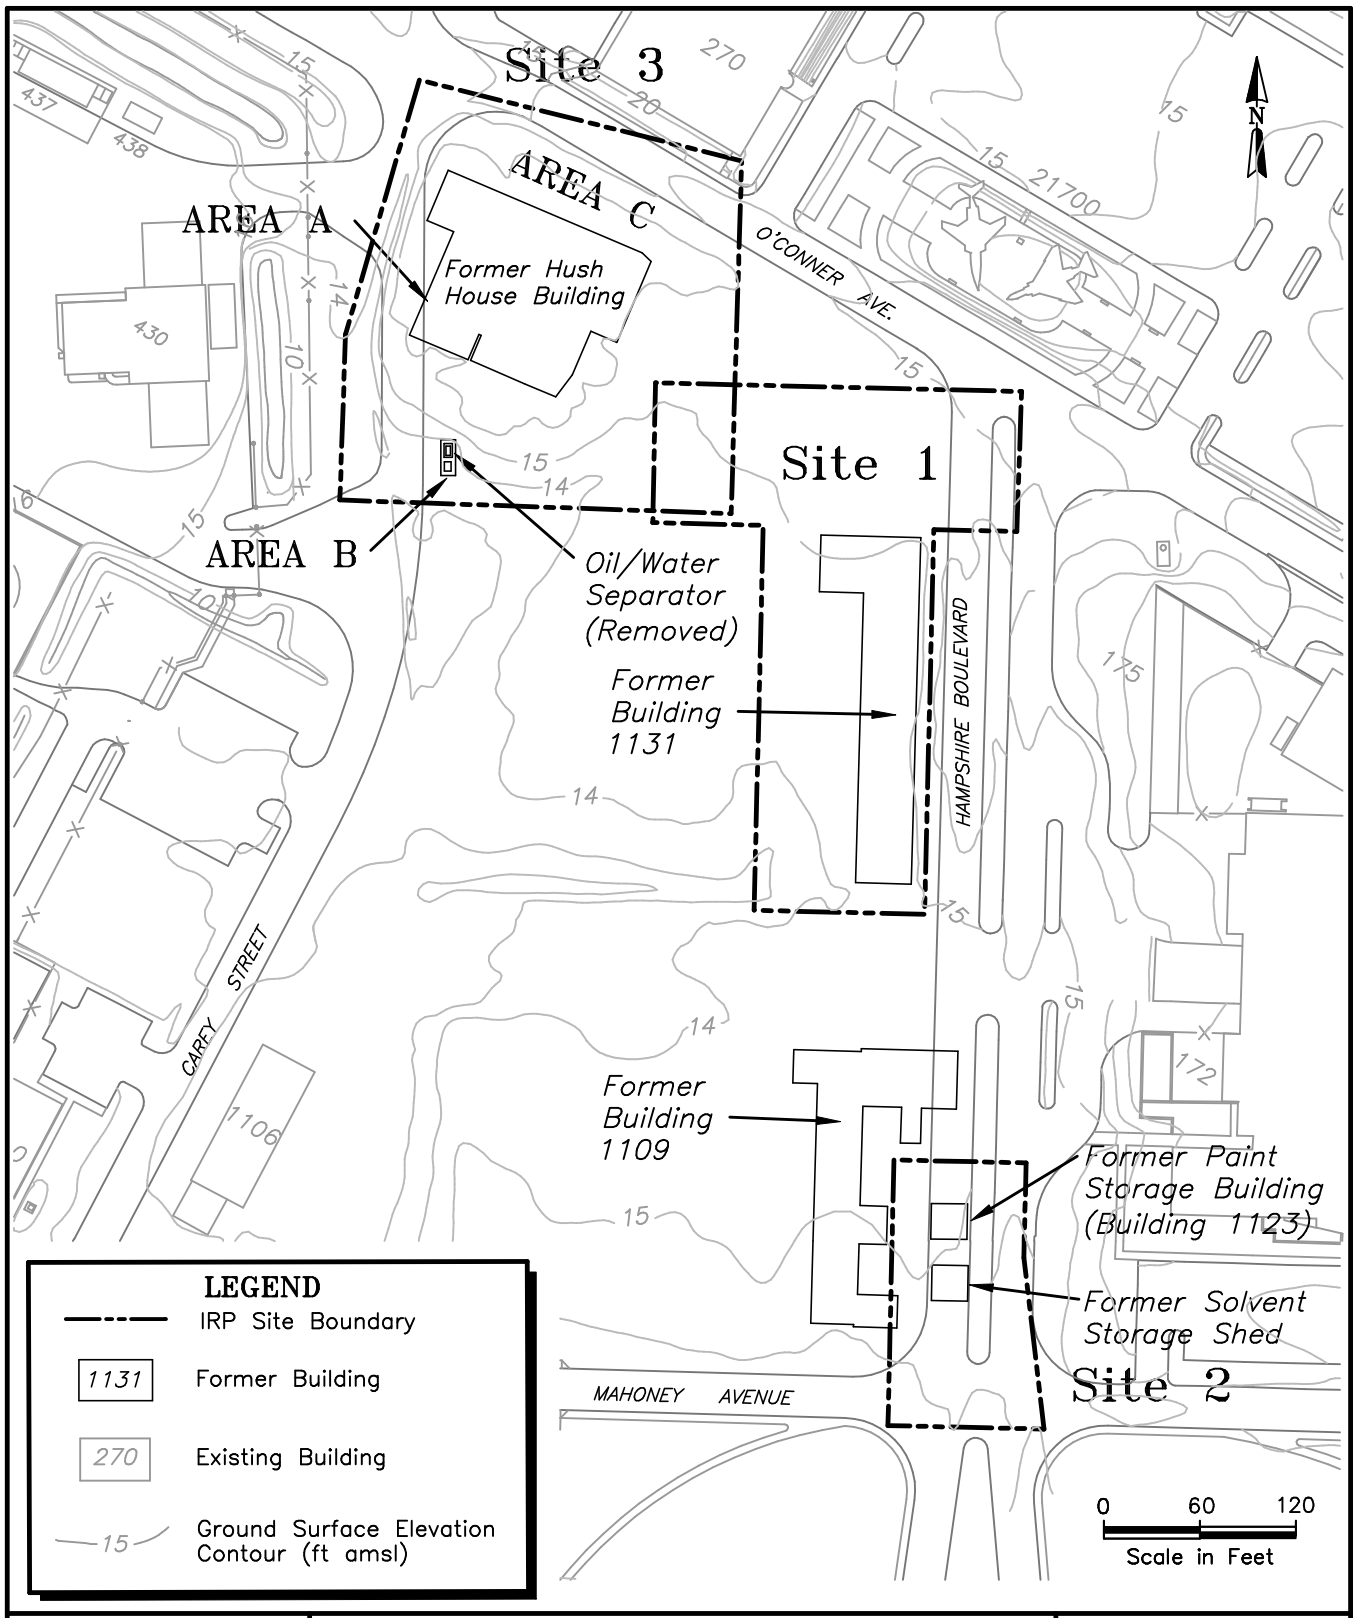
TABLE 3-2



IRP Site Description Summary
142nd FW, Portland ANGB, Portland, Oregon

IRP Site	Site Name	Waste Disposal History	Nature and Extent of Contamination	Risk Assessment Results	Recommendation
1	Central Hazardous Waste Storage Area	Waste storage area for misc. wastes incl. waste oil, solvents, fuels, shop wastes, electrical transformers, and capacitors.	Low levels of TCE, PCE, and cis-1,2-DCE in Shallow Zone groundwater. Likely primary source is IRP Site 2.	Unacceptable total carcinogenic risk and noncarcinogenic hazard for hypothetical on-site residential exposure to groundwater (primarily vinyl chloride).	Soil: No further action. Groundwater: Remedial measures to prevent off-site migration and on-site exposure to groundwater with unacceptable concentrations.
2	Civil Engineering Hazardous Material Storage Area	Solvents, paint thinners, and MEK were stored in or near solvent storage shed; paint was stored in Building 1123.	VOCs not detected in soil samples. Chlorinated VOCs detected in both Shallow Zone and Deep Zone groundwater. Dissolved VOC plume extends approx. 750 feet to northwest and is approximately 400 feet wide.	Unacceptable total carcinogenic risk and noncarcinogenic hazard for hypothetical on-site residential exposure to groundwater (primarily vinyl chloride).	Soil: No further action. Groundwater: Remedial measures to prevent off-site migration and on-site exposure to groundwater with unacceptable concentrations.
3	Hush House Area	Waste oil, fuel, and solvents were stored at the Hush House on unpaved surface.	Area B: Benzene, SVOCs, TPH, and metals detected in shallow soil above PSGs near former oil / water separator. Naphthalene, benzene, and vinyl chloride detected in groundwater above PSGs. Area C: TPH detected in shallow soils.	Unacceptable total carcinogenic risk for hypothetical on-site residential exposure to soil (primarily benzo[a]pyrene and dibenz[a,h]anthracene) and groundwater (primarily benzene and vinyl chloride).	Soil: No further action. Groundwater: Remedial measures to prevent off-site migration and on-site exposure to groundwater with unacceptable concentrations.
4	Main Drainage Ditch	Petroleum and oil were reported in the Main Drainage Ditch downstream from the flight apron outfall in 1987. Ditch receives surface water runoff from adjacent facilities. No records of wastes being intentionally disposed of in the ditch.	SVOCs, TPH, and metals detected in sediment in Main Drainage Ditch above PSGs. Bromodichloromethane, antimony, cadmium, copper, lead, zinc, and cis-1,2-DCE detected in surface water above PSGs.	No unacceptable risks.	No further action.
5	Aerospace Ground Equipment Maintenance Shop	Spent battery acid, solvents, lubricants, antifreeze, cleaning solutions, and automobile fluids were generated at Maintenance Shop. Wastes may have been disposed of along the northern and southern fence lines. Former LUST contained heating oil.	Area A: Chloroform, 1,2-dichlorobenzene, TCE, toluene, and xylene detected in groundwater at low concentrations. Area B: 1,2-DCA, TCE, and metals detected above PSGs in surface and subsurface soil.	No unacceptable risks. One soil sample exceeded USEPA screening level for lead for an unrestricted use scenario.	No further action.
7	Burn Pit Area	Flammable liquids incl. waste oil, JP-4 jet fuel, and solvents were reportedly burned in the pit as part of fire training exercises.	BTEX, SVOCs, and TPH detected in soil in the burn pit area above PSGs. Benzene, PCE, and TPH detected in groundwater.	Unacceptable carcinogenic risk for hypothetical on-site residential exposure to soil (benzo[a]pyrene).	Soil: No further action. Groundwater: Collect one round of groundwater samples for PAH analysis using lower detection limits.
8	Sanitary Landfill	Wastes incl. ordinary shop and building refuse, paint cans, oil and paint residue, batteries, and broken equipment and parts were reportedly disposed of in trenches and buried.	Soil not sampled; evidence of landfilling not confirmed. No confirmed detections of PCBs, VOCs, SVOCs, or metals in groundwater above PSGs.	No unacceptable risks.	No further action.
9	Petroleum, Oil, and Lubricants Facility	Site consisted of 12 JP-4 USTS, 2 diesel ASTs, 1 waste oil UST, and filling stations.	Benzene, ethylbenzene, and PAHs in groundwater detected above PSGs.	Unacceptable total carcinogenic risk for hypothetical on-site residential exposure to soil (benzo[a]pyrene) and groundwater (primarily benzene and PAHs). Unacceptable noncarcinogenic hazard for hypothetical on-site residential exposure to groundwater (primarily benzene).	Soil: No further action. Groundwater: Remedial measures to prevent off-site migration and on-site exposure to groundwater with unacceptable concentrations.
10	Equipment Washrack	Liquids from equipment washing operations discharged via drain pipe to a roadside ditch.	Antimony, cadmium, lead, and selenium detected above PSGs in soil.	No unacceptable risks. One soil sample exceeded USEPA screening level for lead for an unrestricted use scenario.	No further action.
11	Washrack West of Building 250	Liquids from aircraft washing operations flowed from washrack area to the catch basin of the oil / water separator. Prior to removal, cracks were noticed in the oil / water separator.	Soil: Chlorinated VOCs, BTEX, TPH, and metals in area of former oil / water separator. Groundwater: VOCs and petroleum hydrocarbons in Shallow Zone; extend to northwest. Benzene, 1,2-DCA, cis-1,2-DCE, and vinyl chloride detected above PSGs in Deep Zone.	Unacceptable total carcinogenic risk and noncarcinogenic hazard for hypothetical on-site residential exposure to groundwater (primarily benzene, 1,2-DCA, and vinyl chloride).	Soil: In-situ treatment. Groundwater: Remedial measures to prevent off-site migration and on-site exposure to groundwater with unacceptable concentrations.

NOTES:

bgs - Below ground surface
ft - Feet
LUST - Leaking underground storage tank
PCB - Polychlorinated biphenyl
MEK - Methyl ethyl ketone
PCB - Polychlorinated Biphenyl
PSG - Project screening goal
UST - Underground storage tank
SVOC - Semivolatile organic compound
TPH - Total petroleum hydrocarbon

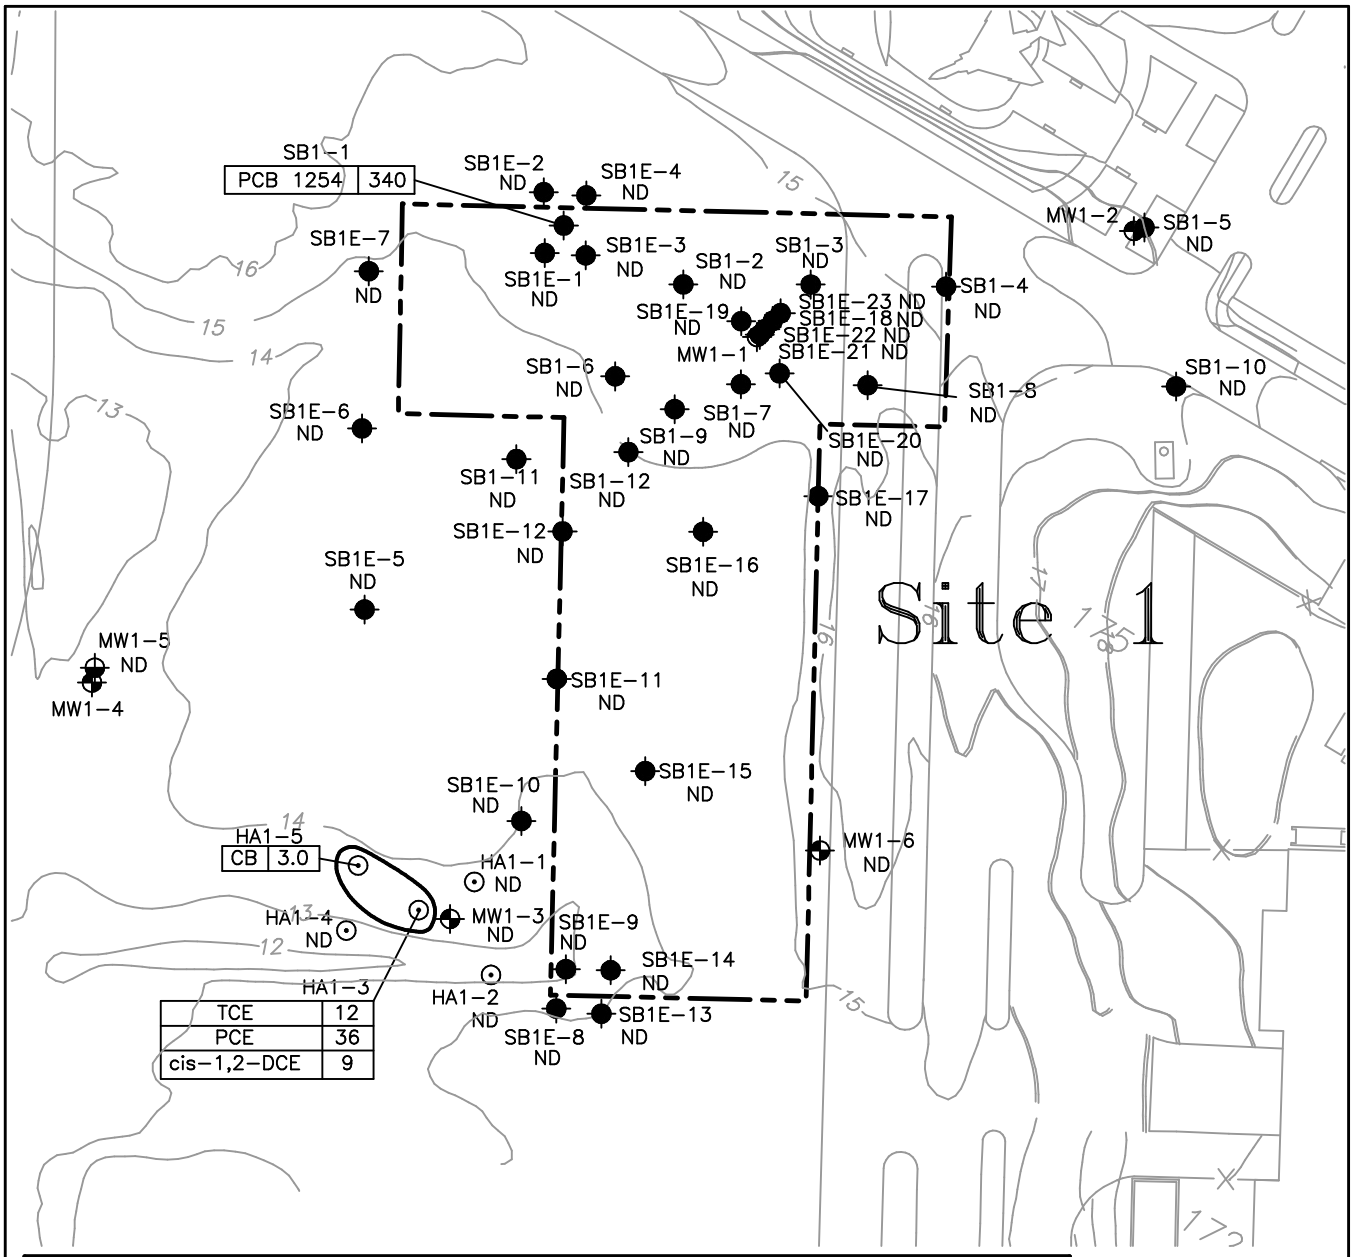
PORTLAND, OREGON

FIGURE 3-1

The surrounding area to the north and west of the site is grassy and unpaved. Hampshire Boulevard intersects the eastern part of the site and O'Conner Way borders the site on the north.

Building 1131 was a wooden structure that was used to store lawn maintenance equipment. An asphalt-paved area on the western side of the building was used for temporary storage of electrical transformers and other miscellaneous equipment.

Underground utility lines, including a new storm sewer, run along the eastern portion of the site. Surface water drains off-site through catch basins on the north and west sides of the site, flows into the Main Drainage Ditch along Carey Street, and is eventually pumped into the Columbia Slough from retention ponds at the west end of the Main Drainage Ditch.



3.1.1 Waste Disposal History

Beginning in 1970, IRP Site 1 was used as a waste storage area for miscellaneous wastes including 55-gallon drums of waste oil, solvents, fuels, shop wastes, electrical transformers, and capacitors. Storage of these materials was suspended in approximately 1990.

3.1.2 Nature and Extent of Contamination

Cis-1,2-DCE and VC were the most prevalent VOCs detected in Shallow Zone groundwater proximal to IRP Site 1. In addition, cis-1,2-DCE was detected below the project screening goal (PSG) in Deep Zone well MW1-5 in July 2000. Based on the observed distribution of chlorinated VOCs in groundwater, IRP Site 2 appears to be the primary source area for the VOCs observed proximal to IRP Site 1. However, a potential secondary source was identified at Site 1 during the Phase II RI: low levels of TCE, tetrachloroethylene (PCE), and cis-1,2-DCE were detected in a soil sample collected within 10 feet of monitoring well MW1-3 (Figure 3-2). Degradation of the TCE detected in soil in this area could act as a source of cis-1,2-DCE and VC in groundwater. Additionally, the single detection of PCE in a sample from monitoring well MW1-3 in 1997 may be related to the PCE detected in soil.

Figure 3-3 shows the extent of VOCs in Shallow Zone groundwater at IRP Sites 1, 2, and 3, observed in April 2000. The VC concentration

in well MW1-3 decreased by an order of magnitude following the initial groundwater sampling event in January 1997, and remained relatively stable through July 1999; the concentration detected in January 2000 was 17.6 µg/l; the concentration detected in April 2000 was 2.09 µg/l. Concentrations of TCE and cis-1,2-DCE in well MW1-3 have remained relatively stable throughout the monitoring program.

3.1.3 Risk Assessment Results

The results of the risk characterization for IRP Site 1 indicate the following:

- The estimated carcinogenic risks for Base workers, construction workers, and reservists are within the range of acceptable risk levels established by the USEPA (i.e., 1×10^{-6} to 1×10^{-4}).[1] Thus, the risks associated with the defined exposures are acceptable under USEPA guidelines. The carcinogenic risks for Base workers, construction workers, and reservists are also less than the ODEQ benchmark of 1×10^{-5} for total risk (i.e., exposure to multiple constituents and/or exposure via multiple pathways), indicating that the estimated carcinogenic risks are acceptable under ODEQ regulations.

- The estimated noncarcinogenic hazards for Base workers, construction workers, and reservists are below the USEPA and ODEQ acceptable hazard level (i.e., the calculated hazard indices are less than 1). Consistent with USEPA guidelines, this indicates that no adverse health effects are anticipated to occur under the defined conditions of exposure.

- The potential carcinogenic risk and noncarcinogenic hazard associated with soil exposures under a conservative residential scenario are less than USEPA and ODEQ guidelines for evaluation of acceptable risk. However, the total carcinogenic risk and noncarcinogenic hazard for hypothetical on-site residents exceed both USEPA and ODEQ levels of acceptable risk, as a result of assumed exposures to groundwater under the residential-use scenario. The risk is primarily associated with the presence of VC in groundwater. By extension of the results

[1] A risk of 1×10^{-6} indicates that there is an upper bound probability of 1 in 1,000,000 (one million) that an individual will develop cancer during his or her lifetime as a result of the defined conditions of exposure. Because of the conservatism of the assumptions used to derive risk estimates, any actual risks associated with a defined exposure are expected to be lower than the estimated risks (USEPA 1989).

for the on-site residential scenario, the potential future risks to off-site residents related to the possible off-site migration and residential use of contaminated groundwater also exceed USEPA and ODEQ criteria.

3.1.4 Recommendation

The risks associated with soil at IRP Site 1 have been determined to be acceptable for all anticipated land-use scenarios. It is therefore recommended that no further action be performed related to soil.

The results of previous investigations at IRP Site 1 have indicated that the VOCs detected in Shallow Zone and Deep Zone groundwater at this site are primarily associated with a VOC plume originating from IRP Site 2. Accordingly, remedial alternatives developed for the VOCs in IRP Site 2 groundwater will include the area of the plume that has migrated onto IRP Site 1.

3.2 IRP Site 2 - Civil Engineering Hazardous Material Storage Area

The former Civil Engineering Hazardous Material Storage Area is east of former Building 1109, as shown on Figure 3-1. The site includes the former locations of the solvent storage shed and the paint storage building (Building 1123). The PA report (HMTC 1987) defined IRP Site 2 as the area between the storage shed and Building 1123; however, during the SI it was determined that the storage shed itself may also have been a source of contamination (SAIC 1991). The solvent storage shed consisted of an open-walled structure with a gravel floor. The storage shed and Building 1123 were removed during non-IRP-related construction activities.

Currently, IRP Site 2 is situated largely in the roadway of Hampshire Boulevard immediately north of the intersection with Mahoney Avenue. The former locations of the solvent storage shed and Building 1123 are in the southbound lanes of Hampshire Boulevard. Underground utilities and storm drains run along the eastern and western sides of Hampshire Boulevard. Site topography is relatively flat.

3.2.1 Waste Disposal History

Drums containing solvents, paint thinners, and methyl ethyl ketone were stored on wooden pallets in the solvent storage shed, and on a rack within the shed (HMTC 1987); paint was stored in Building 1123. There are no reports of waste disposal activities.

3.2.2 Nature and Extent of Contamination

Chlorinated VOCs (primarily TCE; cis-1,2-DCE; and VC) were detected in groundwater in both the Shallow Zone and the Deep Zone at IRP Site 2. The highest concentrations of TCE; cis-1,2-DCE; and VC were detected near the former location of the solvent storage shed. This suggests that the dissolved VOCs originated from past releases in the vicinity of the solvent storage shed. VOCs were not detected in soil samples collected in this area during the Phase II RI, possibly because near-surface soils at Site 2 were removed during road construction activities.

The groundwater data indicate that dissolved VOCs have migrated mainly toward the northwest from the apparent source area at IRP Site 2. This migration pattern is consistent with the local direction of groundwater flow in the Shallow Zone. The dissolved VOC plume extends approximately 750 feet downgradient of IRP Site 2, and is approximately 400 feet wide. Figures 3-3 and 3-4 show the lateral and vertical extent of chlorinated hydrocarbons in groundwater. The absence or relatively low concentrations of VOCs in direct-push groundwater samples collected to the southwest, south, and southeast of Site 2 provides additional evidence that the VOC source area is at Site 2.

Concentrations of TCE and cis-1,2-DCE have varied significantly in source-area Shallow zone wells MW2-1 and MW2-2 over the monitoring period; concentrations of VC in piezometer PZ2-1 have also varied significantly.

Deep Zone wells / piezometers in the vicinity of IRP Site 2 include PZ2-2, MW2-4, MW1-5, and MW2-10. The consistent detections of VC above the PSG in piezometer PZ2-2, and the cis-1,2-DCE detections in wells MW1-5 and MW2-10 in July 2000, indicate that dissolved VOCs have migrated to the Deep Zone directly beneath and northwest of IRP Site 2.

There have been no confirmed detections of contaminants in the CRSA wells in the vicinity of IRP Site 2 (MWBG-7 and MWBG-10).

IRP SITES 1, 2, AND 3
VERTICAL DISTRIBUTION OF TOTAL CHLORINATED HYDROCARBONS IN GROUNDWATER
APRIL 2000
142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 3–4

A source of the total petroleum hydrocarbon (TPH) as diesel detected in groundwater samples from several of the IRP Site 2 monitoring wells was not identified in soil. Soils containing residual hydrocarbons may have been removed during road construction activities. During monitoring events conducted in February 1998 and March 1999, TPH as diesel was detected in samples from monitoring well MW2-7, located immediately north of IRP Site 9. The presence of TPH as diesel at this well may be related to petroleum contamination identified at IRP Site 9.

With the exception of isolated detections of benzene (0.7 to 3 µg/l) in piezometers PZ2-1 and PZ2-2, and a single detection of toluene (0.6 µg/l) in piezometer PZ2-1, petroleum-related VOCs and semivolatile organic compounds (SVOCs) were not detected in the IRP Site 2 monitoring wells.

Buried utilities are present near IRP Site 2, particularly at the intersection of Mahoney Avenue and Hampshire Boulevard. These utilities may provide a preferential pathway for VOC vapors to travel a small distance away from the source of those vapors. If deep enough, the utility channels may allow groundwater to flow a short distance away from the general flow path. However, would need to be buried at the depth required (below approximately 12 feet bgs) to have any effect on groundwater contaminant flow direction. The apparent contaminant distribution from the source area at IRP Site 2 is relatively uniform, indicating that preferential pathways resulting from the presence of buried utilities are not affecting distribution of contaminants. Remedial action at this site will require consideration of the presence of buried utilities.

3.2.3 Risk Assessment Results

The results of the risk characterization for IRP Site 2 indicate the following:

- Both the estimated carcinogenic risks and the noncarcinogenic hazards are acceptable for Base workers, construction workers, and reservists under USEPA and ODEQ guidelines.

- The potential carcinogenic risk and noncarcinogenic hazard associated with soil exposures under a conservative residential scenario are less than USEPA and ODEQ guidelines for evaluation of acceptable risk. However, the total carcinogenic risk and noncarcinogenic hazard for hypothetical on-site residents exceed both USEPA and ODEQ levels of acceptable risk, as a result of assumed exposures to groundwater under the residential-use scenario. The risk is primarily associated

with the presence of VC in groundwater. By extension of the results for the on-site residential scenario, the potential future risks to off-site residents related to the possible off-site migration and residential use of contaminated groundwater also exceed USEPA and ODEQ criteria.

- Reported lead concentrations in soil were below the USEPA screening level of 400 milligrams per kilogram (mg/kg) for an unrestricted-use scenario (USEPA Region 9 2000); thus lead in soil is not expected to pose an unacceptable risk.

3.2.4 Recommendation

The risks associated with soil at IRP Site 2 have been determined to be acceptable for all anticipated land-use scenarios. It is therefore recommended that no further action be performed related to soil.

As discussed, previous investigations have indicated that the VOCs in groundwater in the area of IRP Sites 1 and 2 have originated from releases at the former solvent storage shed at IRP Site 2. In addition, previous investigations also indicate a probably correlation between VOCs in groundwater at IRP Site 3 (as discussed in Section 3.3) and releases at the former solvent storage shed. As such, the VOCs in groundwater at IRP Sites 1, 2, and 3 will be addressed in this FS as one plume, and referred to as IRP Site 2 groundwater.

Anticipating the need to conduct an FS for groundwater at IRP Site 2, the IRAC program described in Section 2.8.2 was initiated for the purpose of providing data from which to base decisions made during the FS process. The first phase of the IRAC provided bench- and pilot-scale treatability data indicating that chemical and biological treatment technologies are effective at reducing VOC concentrations in groundwater at IRP Site 2. Using these results, a presumptive approach was taken to select potential remedies for VOCs in groundwater. The second phase of the IRAC program is expected to be conducted during the fall of 2001 and will provide full-scale treatability data to be used to adjust some of the recommendations made during this FS prior to full-scale RA construction.

The second phase of the IRAC program is also intended to significantly reduce the mass of VOCs at IRP Site 2. The full-scale demonstration will focus on a large area of Shallow Zone groundwater containing the highest concentrations of VOCs (ERM 2001d). Implementation of this demonstration is expected to reduce the potential for migration of VOCs to downgradient areas of the Shallow Zone and to the Deep Zone.

Although a significant reduction of VOCs is expected during the second phase of the IRAC program, a conservative position is taken in this FS by not considering this reduction during the development and evaluation of the remedial alternatives presented later in the document.

Due to the extent and concentrations of VOCs in Shallow Zone and Deep Zone groundwater originating from IRP Site 2, remedial alternatives were developed based on technologies known to be effective at treating VOCs in groundwater. Identification and screening of technologies are presented in section 4.0 of this FS. Development and evaluation of remedial alternatives are presented in section 5.0 of this FS.

3.3 IRP Site 3 - Hush House Area

The former Hush House Area is at the southeast corner of the intersection of Carey Street and O'Conner Way, as shown on Figure 3-1. The Hush House building was used to test the performance of jet engines. An oil/water separator existed approximately 75 feet south of the Hush House. An exhaust tower and associated piping from the condensation system drained into the oil/water separator and a holding tank.

During the SI, the former Hush House building was designated as Area A, the oil/water separator was designated as Area B, and an area to the northeast of the former Hush House, where petroleum hydrocarbon contamination was encountered during construction activities, was designated as Area C.

The ground surface across most of IRP Site 3 is approximately 2 to 3 feet higher than the surrounding area, and generally slopes toward the south and east. Site surface water drains into the Main Drainage Ditch through a culvert that passes under Carey Street to the west.

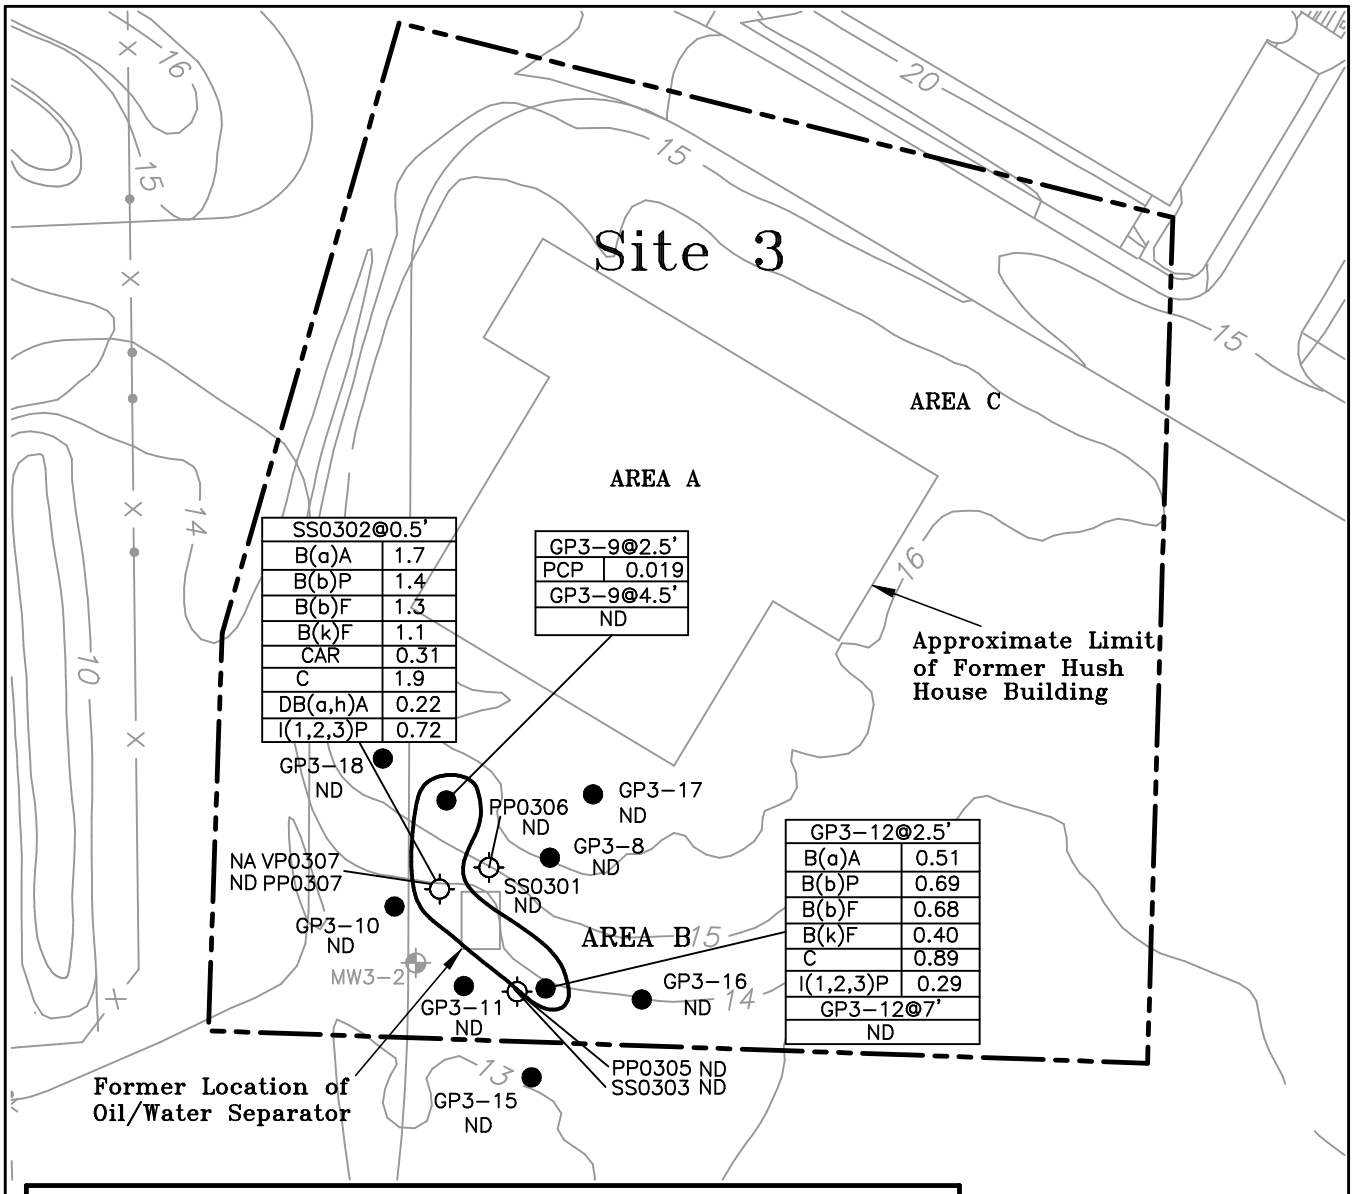
3.3.1 Waste Disposal History

Drums of waste oil, fuel, and solvents were reportedly stored at the southwest corner of the Hush House on an unpaved surface (SAIC 1991). Base personnel interviewed during the PA indicated that the oil/water separator did not function properly. No records were available concerning removal of liquids from the separator or the associated holding tank (HMTC 1987).

3.3.2 Nature and Extent of Contamination

The results of the Phase II RI and previous investigations at IRP Site 3 are discussed below.

3.3.2.1 Area A, Former Hush House Building



No confirmed contaminants were detected in the soil and groundwater samples collected at Area A during the SI, consequently, no further investigation of this area was performed during the Phase I or II RIs.

3.3.2.2 Area B, Former Oil/Water Separator

Constituents detected above PSGs in soil samples collected at Area B include benzene, petroleum-related SVOCs, TPH as diesel, and metals. SVOC, TPH, and metal concentrations detected in soil samples are shown on Figures 3-5, 3-6, and 3-7 respectively. The RI sampling indicates that the lateral extent of soils impacted by compounds exceeding PSGs is limited to within 30 to 40 feet of the former oil / water separator. Although the lateral extents of TPH and SVOC impacts are almost identical, the data indicate that the maximum TPH concentrations occur at a depth of approximately 8 feet bgs, whereas SVOCs are primarily limited to the upper 2.5 to 3 feet of soil. Metal concentrations exceeding PSGs also are limited to the upper 2.5 to 3 feet of soil.

Petroleum-related SVOCs and TPH as diesel were detected in soils potentially in contact with groundwater. However, only naphthalene and benzene were detected above PSGs in groundwater samples. The naphthalene and benzene were detected close to borings PP0306 and PP0307, in which the highest TPH concentrations in soil were detected close to the water table. TPH-related groundwater impacts are limited to within 10 to 20 feet of the former oil / water separator.

Although VC and other chlorinated VOCs were detected in groundwater at Area B, chlorinated VOCs were not detected in soil. This indicates that the former oil / water separator is not likely a source of the chlorinated VOCs. Further, the presence of chlorinated VOCs in groundwater at IRP Site 3 is likely associated with Site 2 groundwater (Figure 3-3).

3.3.2.3 Area C, Construction Area

TPH as Jet Fuel A, TPH as diesel, and/or TPH as heavy oil were detected in soil samples collected from borings PP0301, PP0304, and HA3-3. Detections above PSGs include TPH as diesel (490 mg/kg) in the sample collected from 3 feet bgs in boring HA3-3, and TPH as heavy oil in the samples collected from 2.5 feet bgs (118 mg/kg) and 5 feet bgs (127 mg/kg) in boring GP3-19. TPH detections in soil are shown on Figure 3-6. VOCs and SVOCs were not detected in the groundwater sample collected from boring GP3-3.

3.3.3 Risk Assessment Results

The results of the risk characterization for IRP Site 3 indicate the following:

- Both the estimated carcinogenic risks and the noncarcinogenic hazards are acceptable for Base workers, construction workers, and reservists under USEPA and ODEQ guidelines.

- The total estimated carcinogenic risk for hypothetical on-site residents exceeds USEPA and ODEQ acceptable levels, primarily as a result of assumed exposures to benzo(a)pyrene and dibenz(a,h)anthracene in soil and benzene and VC in groundwater under this scenario. By extension of the results for the on-site residential scenario, the potential future carcinogenic risk to off-site residents related to the possible off-site migration and residential use of contaminated groundwater also exceeds USEPA and ODEQ criteria. The total noncarcinogenic hazard is acceptable for both hypothetical on-site residents and off-site residents under USEPA and ODEQ guidelines.

- Reported lead concentrations in soil were below the USEPA screening level for an unrestricted-use scenario; thus lead in soil is not expected to pose an unacceptable risk.

3.3.4 Recommendation

No confirmed contaminants have been detected in soil or groundwater at Area A. It is therefore recommended that no further action be performed at this location.

Soil at Area B in the location of the former oil/water separator contains several contaminants above the PSGs. However, the risk associated with soil in this area is acceptable based on an industrial land-use scenario. It is not expected that the industrial land use of this area will change in the near future (City of Portland 2000).

The results of previous investigations at Area B have indicated that the VOCs detected in groundwater at this site are primarily associated with the VOC plume originating from IRP Site 2, rather than from soil contamination at Area B. As previously mentioned, the area of the plume that has migrated onto IRP Site 3 will be addressed in the remedial alternatives developed for VOCs in IRP Site 2 groundwater.

Area C soil has had detections of petroleum hydrocarbons exceeding the respective PSGs for these constituents. However, because of the small volume of impacted soil and the current and anticipated industrial land use, it is recommended that no further action be performed at this location.

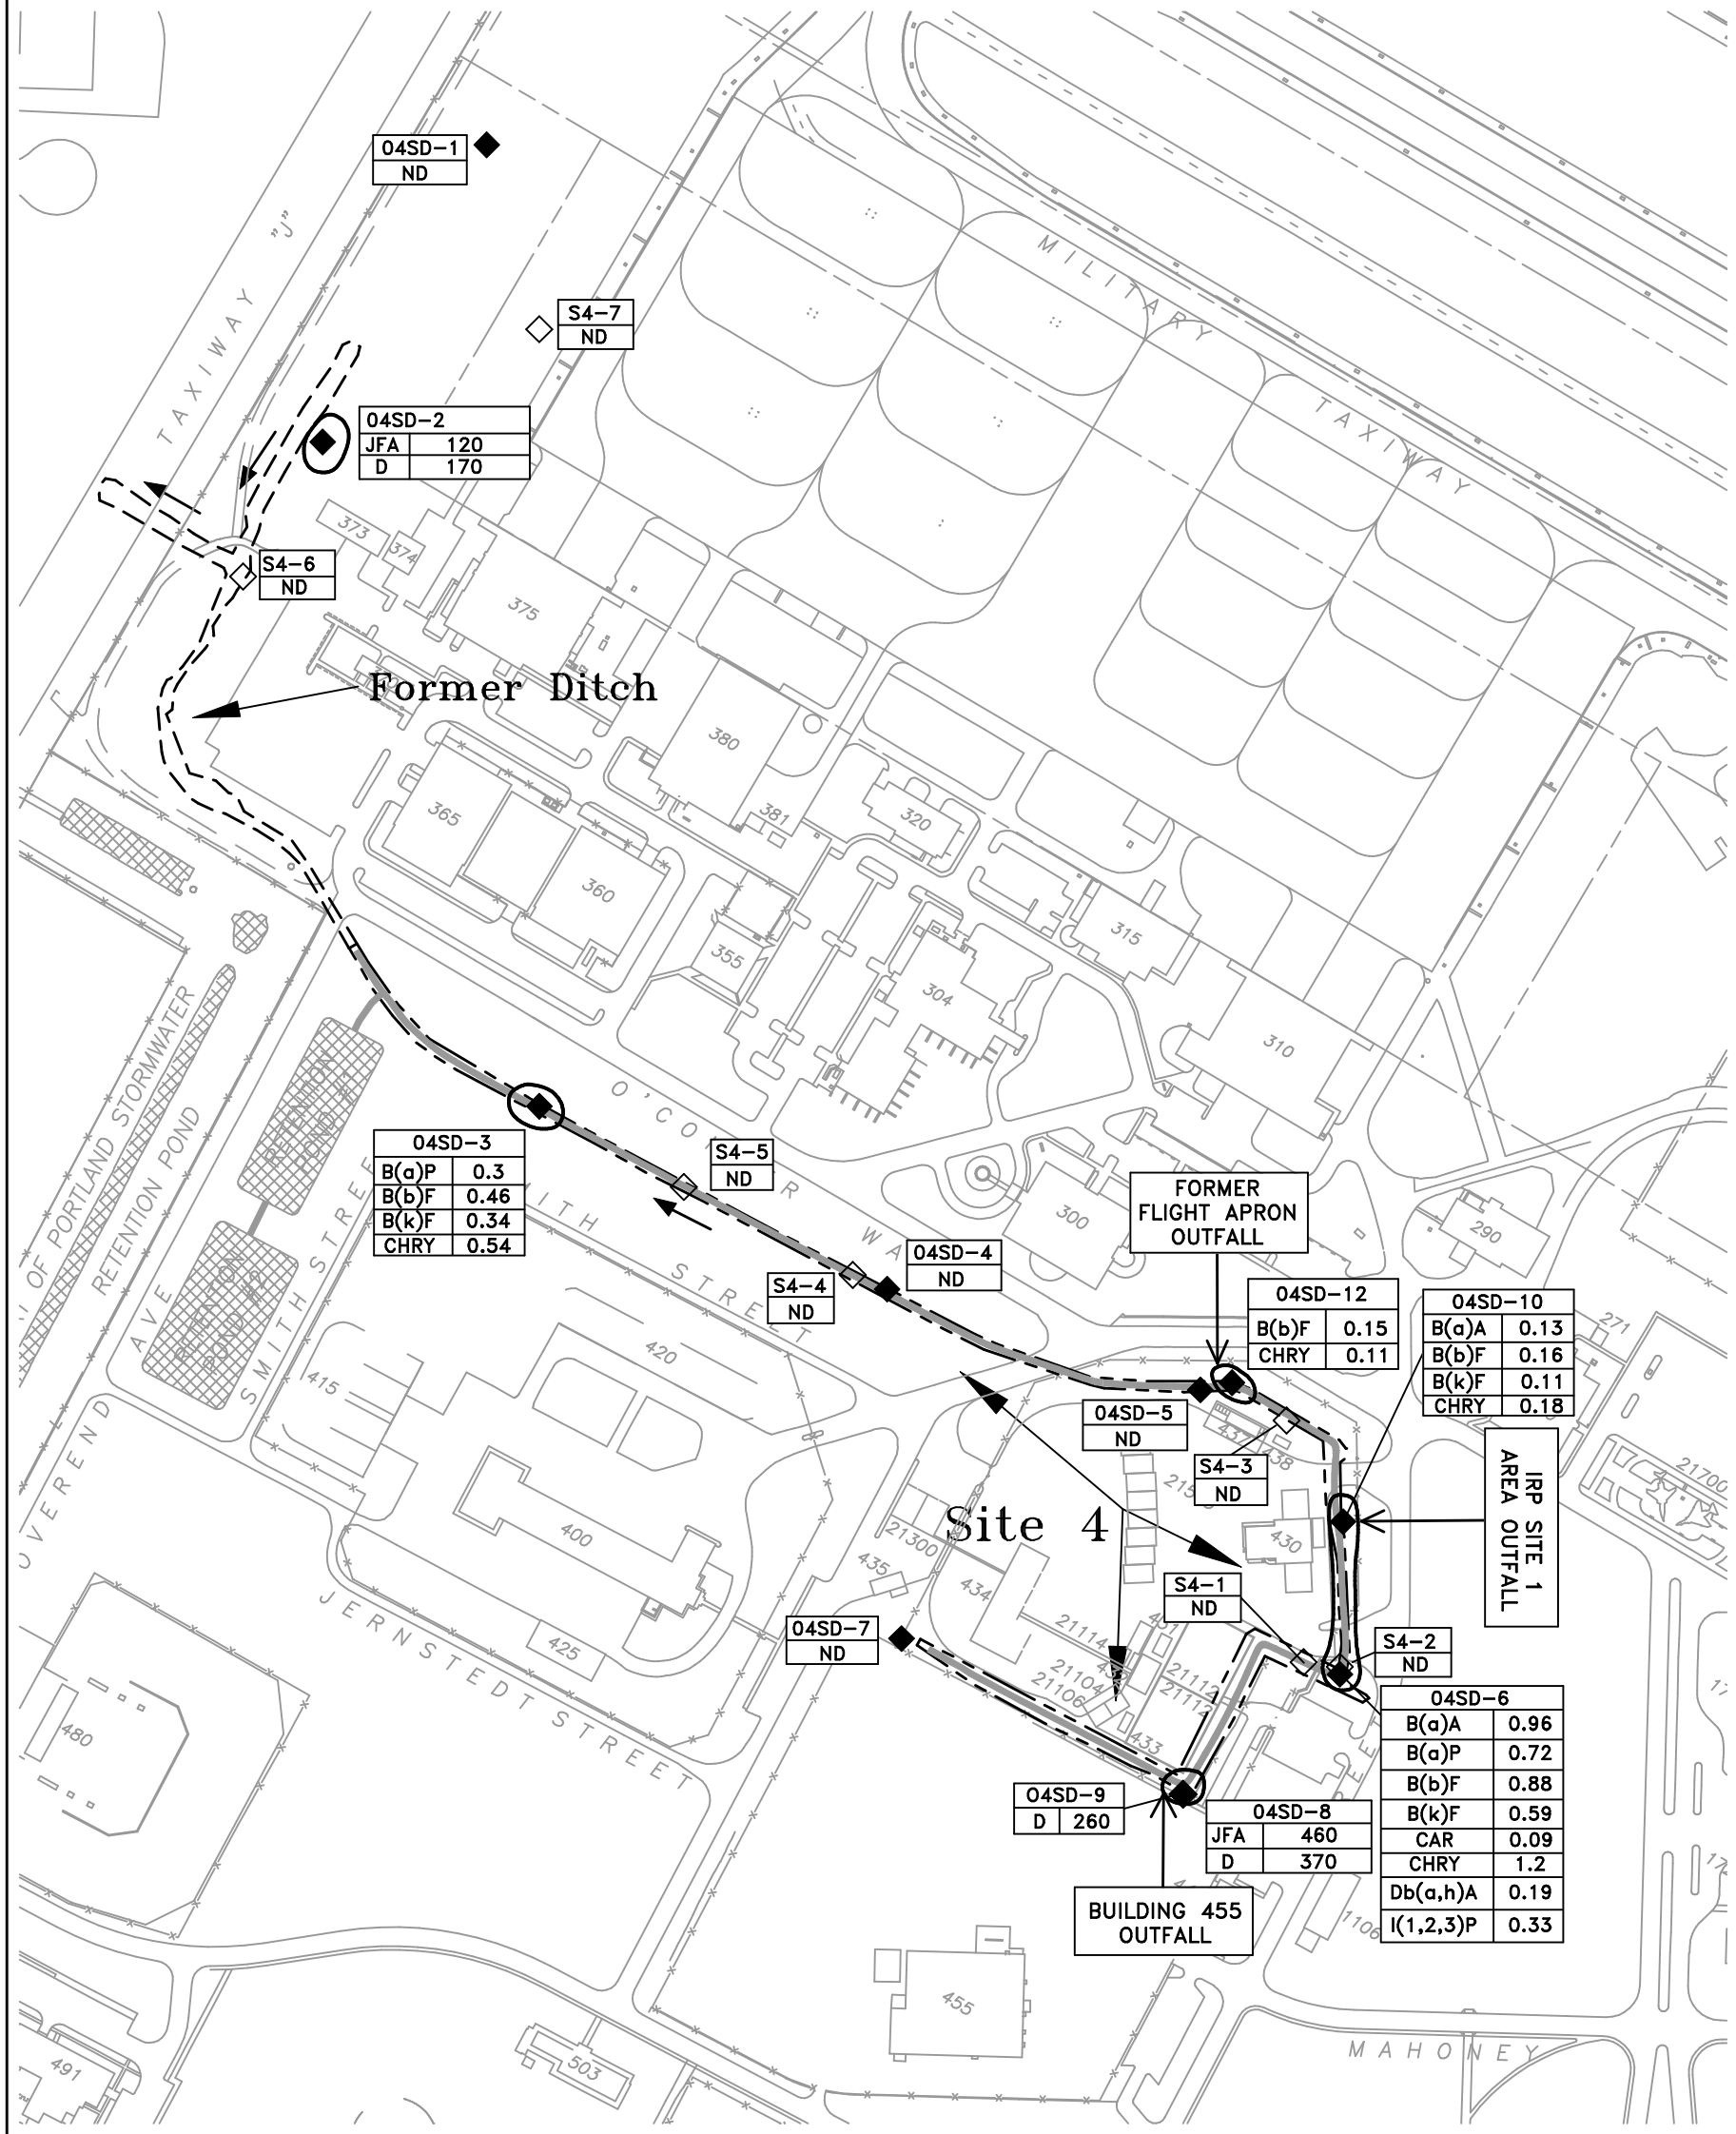
3.4 IRP Site 4 - Main Drainage Ditch

The Main Drainage Ditch in the western-central portion of the Portland ANGB receives surface water runoff from catch basins and drainage ditches across most of the Base. The water in the Main Drainage Ditch flows to two retention ponds near the western Base boundary. Water from the retention ponds is pumped into a ditch west of the Base that discharges into the Columbia Slough.

3.4.1 Waste Disposal History

During initial field surveillance activities and sampling, HMTC (1987) reported the presence of petroleum and oil in the Main Drainage Ditch downstream from the flight apron outfall. Accidental spillage, indirect discharge, and wash water containing residual contaminants from facilities adjacent to the ditch may have impacted storm water and sediments in the ditch (SAIC 1991). There are no records of wastes being intentionally disposed of in the ditch.

3.4.2 Nature and Extent of Contamination



Investigation results at IRP Site 4 indicate that sediment in the Main Drainage Ditch contains SVOCs, TPH, and metals above the respective PSGs. Surface water samples collected at Site 4 during the RI were found to contain bromodichloromethane, cis-1,2-DCE, antimony, cadmium, copper, lead, and/or zinc above the respective PSGs.

The majority and highest concentrations of SVOCs were detected in sediment in the eastern portion of the ditch (samples 04SD-6, 04SD-9, 04SD-10, and 04SD-12). This portion of the ditch receives surface runoff from several storm drain outfalls (Figure 3-8). SVOCs also were detected above respective PSGs in sediment sample 04SD-3 collected near the central portion of the ditch. SVOCs, however, either were not detected or were detected below PSGs in the two sediment samples (04SD-4 and 04SD-5) collected immediately upstream of this location. The source of the SVOCs detected in sample 04SD-3 is unclear.

TPH as diesel was detected above the PSG in three sediment samples (04SD-2, 04SD-8, and 04SD-9) collected from the Main Drainage Ditch (Figure 3-8). Sample 04SD-2 was collected at the former west end of the ditch at the discharge point for surface water runoff originating from the Base parking lots. Samples 04SD-8 and 04SD-9 were collected at the east end of the ditch, below the outfall of a drain line that originates in the area of the Base motor pool (Building 455). The highest concentration of TPH as diesel detected was 370 mg/kg (sample 04SD-8).

Metals were detected above respective PSGs in the majority of the sediment samples collected from the Main Drainage Ditch (Figure 3-9). Cadmium was the metal most frequently detected above PSGs. The highest concentrations of metals were detected in sample 04SD-8, which was collected below the Building 455 outfall.

Bromodichloromethane and dissolved metals (antimony, cadmium, copper, lead, and zinc) were detected above respective PSGs in surface water samples collected during the Phase I RI. Cis-1,2-DCE was detected above the PSG in one surface water sample, and zinc was detected above the PSG in two surface water samples collected during the Phase II RI. The presence of detectable organic compounds and metals in the ditch water likely depends on a variety of factors, including seasonal precipitation patterns and surface water flow rates. Metals detected above PSGs in surface water are shown on Figure 3-10. There is no apparent correlation between the concentrations of metals detected in surface water and those detected in sediment near the same locations.

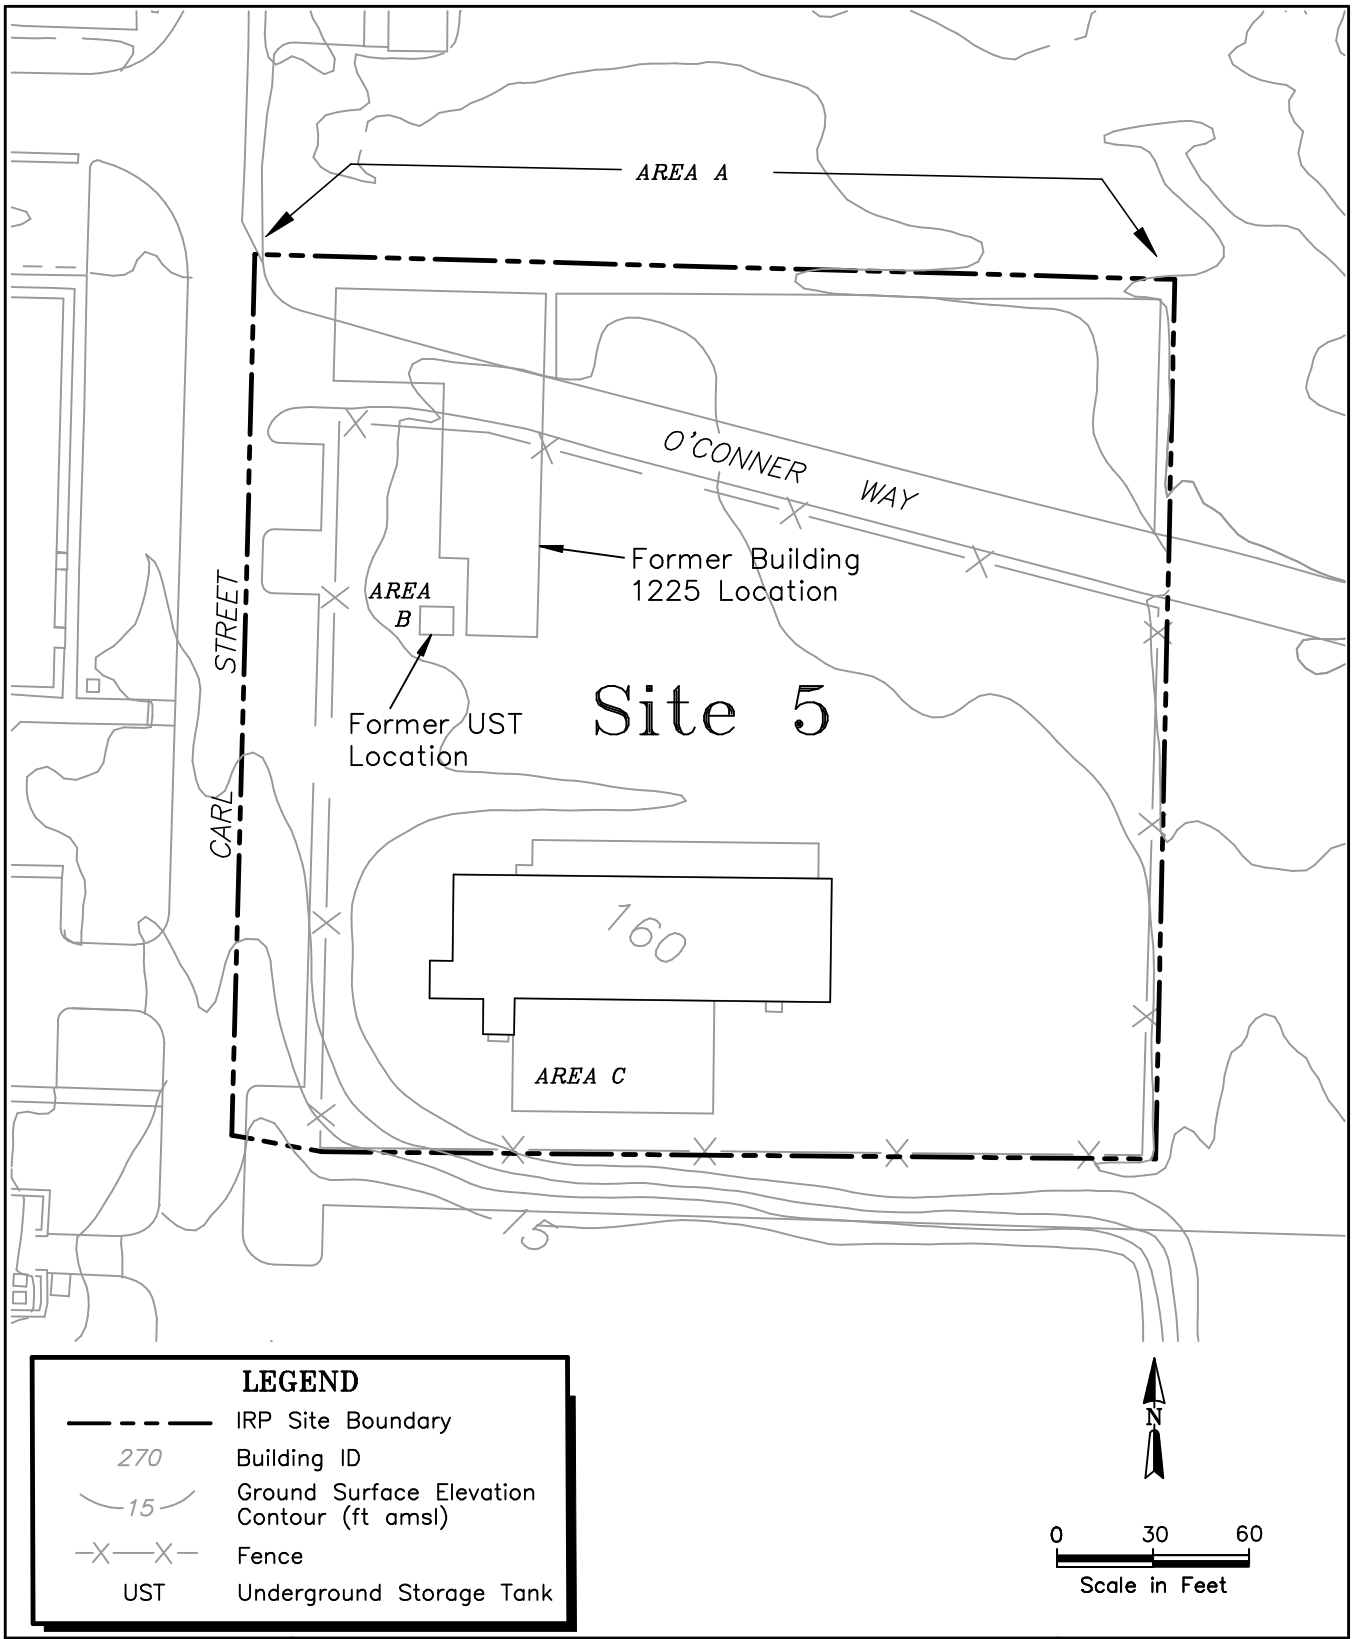
FIGURE 3-10

3.4.3 Risk Assessment Results

The results of the risk characterization for IRP Site 4 indicate that the estimated carcinogenic risk and the noncarcinogenic hazard are acceptable for construction workers under USEPA and ODEQ guidelines. The results of the screening-level ecological risk assessment indicate that contaminants detected in surface water and sediment in the Main Drainage Ditch do not pose unacceptable risks to on-site ecological receptors. However, because off-site habitats are considered to be of moderate-to-high value to wildlife, further monitoring of the potential for contaminants to migrate from the Main Drainage Ditch to off-site habitats is warranted. In addition, a Level II (screening) ecological risk assessment is planned to further evaluate potential risks to ecological receptors at the Main Drainage Ditch.



3.4.4 Recommendation

No unacceptable risks were identified at IRP Site 4. However, based on a recommendation made in the RI, monitoring of the potential for contaminants to migrate from the Main Drainage Ditch to off-site habitats will be continued. Based on recommendations from DEQ, the Level II ecological risk assessment mentioned above will be performed to verify the lack of impacts to ecological receptors at the Main Drainage Ditch.

3.5 IRP Site 5 - Aerospace Ground Equipment Maintenance Shop

Liquid wastes were reportedly disposed of to the ground surface at points along two fence lines at the AGE Maintenance Shop. One area (Area A) is north of O'Conner Way, and the second (Area C) is approximately 50 feet south of Building 160 (Figure 3-11). The former location of a leaking UST is designated as Area B. The UST, Building 1225, and the northern fence line were removed in 1988. O'Conner Way separates the remainder of IRP Site 5 from the former northern fence line.

The topography at IRP Site 5 is relatively flat with a slight slope toward the north and the east. Stormwater catch basins exist near the eastern and southern site boundaries. There are storm sewer and water lines along the east side of Carl Street, and buried power lines along O'Conner Way.

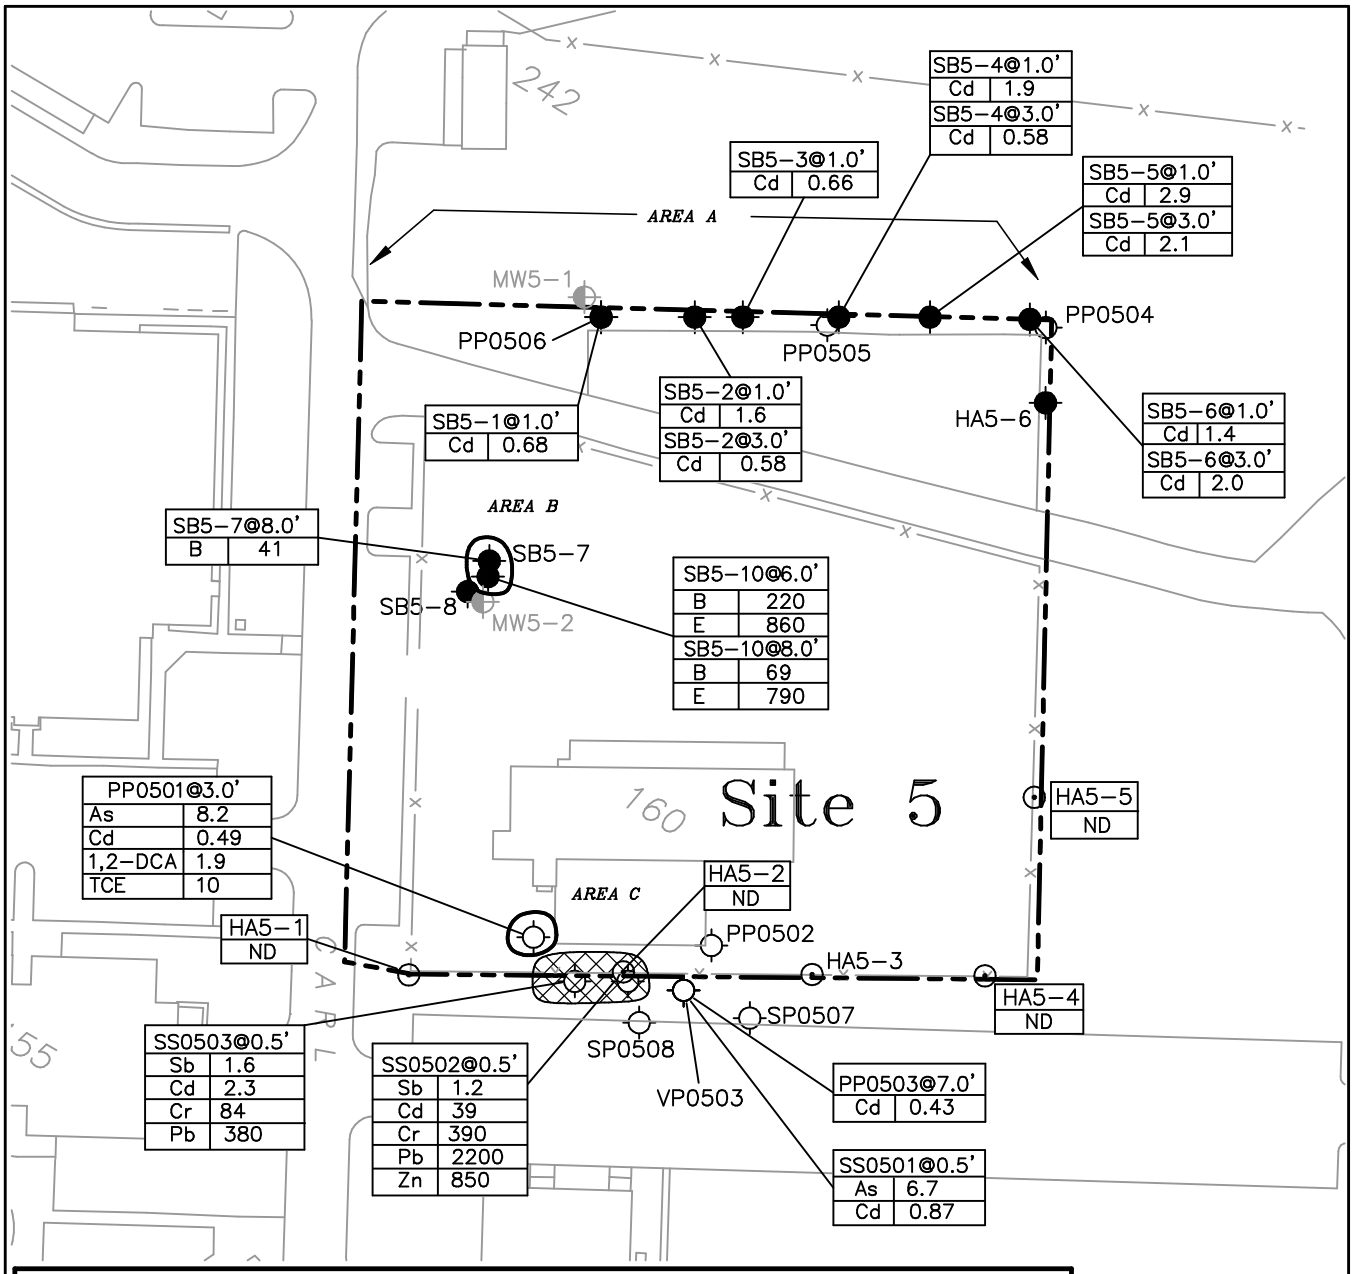
FIGURE 3-11

3.5.1 Waste Disposal History

Wastes generated at the AGE Maintenance Shop include spent battery acid, solvents, lubricants, antifreeze, cleaning solutions, and automobile fluids. Some of these wastes may have been disposed of along the northern and southern fence lines as evidenced by soil staining (HMTC 1987). The former leaking UST contained heating oil, and was excavated and removed in late 1988.

3.5.2 Nature and Extent of Contamination



The results of the investigations conducted at Areas A and C are discussed below. Area B was not investigated as part of the IRP; this area is being addressed through the Base's UST program.

3.5.2.1 Area A, Former Northern Fence Line

The soil investigations conducted at Area A have not found conclusive evidence to indicate that wastes were discharged to the ground surface along the northern fence line. Although cadmium was detected above the PSG in ten of the twelve soil samples collected along the former fence line (Figure 3-12), the frequency of the detections suggests that the elevated cadmium levels may be associated with imported fill material or native soil conditions in the vicinity of IRP Site 5.

TCE was detected above the PSG in groundwater samples collected from monitoring well MW5-1 in December 1988 at a concentrations of 6.2 µg/l, and in April 1996 at a concentration of 2.5 µg/l. In May 1996, TCE also was detected below the PSG in direct-push groundwater sample PP0506 (located within 5 to 10 feet of monitoring well MW5-1) 1 at a concentration of 1.3 µg/l. TCE was not detected in well MW5-1 during the Phase II RI. Concentrations of chloroform; 1,2-dichlorobenzene; toluene; and xylene were each detected in samples collected from well MW5-1, at concentrations of 2.0 µg/l or less. Five reported detections of methylene chloride (0.49 to 8.5 µg/l) in IRP Site 5 groundwater samples are suspected laboratory artifacts.

The source of the VOCs detected in groundwater is uncertain, but the absence of VOCs in soil indicates that Area A is not a likely source. The VOCs and TPH as diesel detected in monitoring well MW5-1 may be related to the former leaking UST at Area B.

PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 3-12

3.5.2.2 Area C, Southern Fence Line

The constituents 1,2-dichloroethene (1,2-DCA) and TCE were detected above respective PSGs in the soil sample collected from 3 feet bgs in boring PP0501. VOCs were not detected in the soil sample collected from 7 feet bgs in boring PP0501, nor were VOCs detected in other soil samples collected at Area C.

Antimony, arsenic, cadmium, chromium, lead, and/or zinc were detected above respective PSGs in three surface soil samples and two subsurface soil samples collected at Area C during the Phase I RI. As discussed above, the frequency of cadmium detections above the PSG at IRP Site 5 suggests that the elevated cadmium levels may be associated with imported fill or native soil conditions in the area. Additionally, although arsenic was detected above the PSG in one surface soil sample and one subsurface soil sample, these detections were not associated with elevated concentrations of other metals. This suggests that the elevated arsenic levels may also be naturally-occurring.

The concentrations of antimony, cadmium, chromium, and lead in surface soil samples SS0502 and SS0503, and zinc in sample SS0502, are higher than area background concentrations of these metals, and may be indicative of local surface soil contamination. The lateral extent of the apparent contamination is shown on Figure 3-12. The absence of metals detected above respective PSGs in the soil sample collected from 1.5 feet bgs in boring HA5-2 indicates that the vertical extent of contamination is limited to approximately the upper 1 foot of soil.

3.5.3 Risk Assessment Results

The results of the risk characterization for IRP Site 5 indicate the following:

- Both the estimated carcinogenic risks and the noncarcinogenic hazards are acceptable for Base workers, construction workers, reservists, hypothetical on-site residents, and by extension, off-site residents, under USEPA and ODEQ guidelines.

- With one exception, reported lead concentrations in soil were below the USEPA screening level of 400 mg/kg for an unrestricted-use scenario. An isolated detection of lead at 2,200 mg/kg exceeded this screening level, as well as the 750 mg/kg industrial-use screening

level. Analytical results for adjacent soil samples confirm that this is an isolated detection.

3.5.4 Recommendation

Because Area A has had only sporadic detections of VOCs in groundwater, and the frequent detections of cadmium in soil likely are associated with background soil conditions, no further action is recommended for this location.

The risks associated with groundwater at IRP Site 5 have been determined to be acceptable for all anticipated land and water use scenarios. It is therefore recommended that no further action be performed related to groundwater.

3.6 IRP Site 6 – Washrack West of Building 1355

The PA report recommended no further action at IRP Site 6 based on the results of the Phase I Records Search (HMTC 1987). IRP Site 6 was subsequently redesignated as IRP Site 11 during the SI (OpTech 1996) after TPH and metals were detected in soil samples collected by Base personnel during the installation of underground utilities near the washrack. IRP Site 11 is discussed in Section 3.11.

3.7 IRP Site 7 - Burn Pit Area

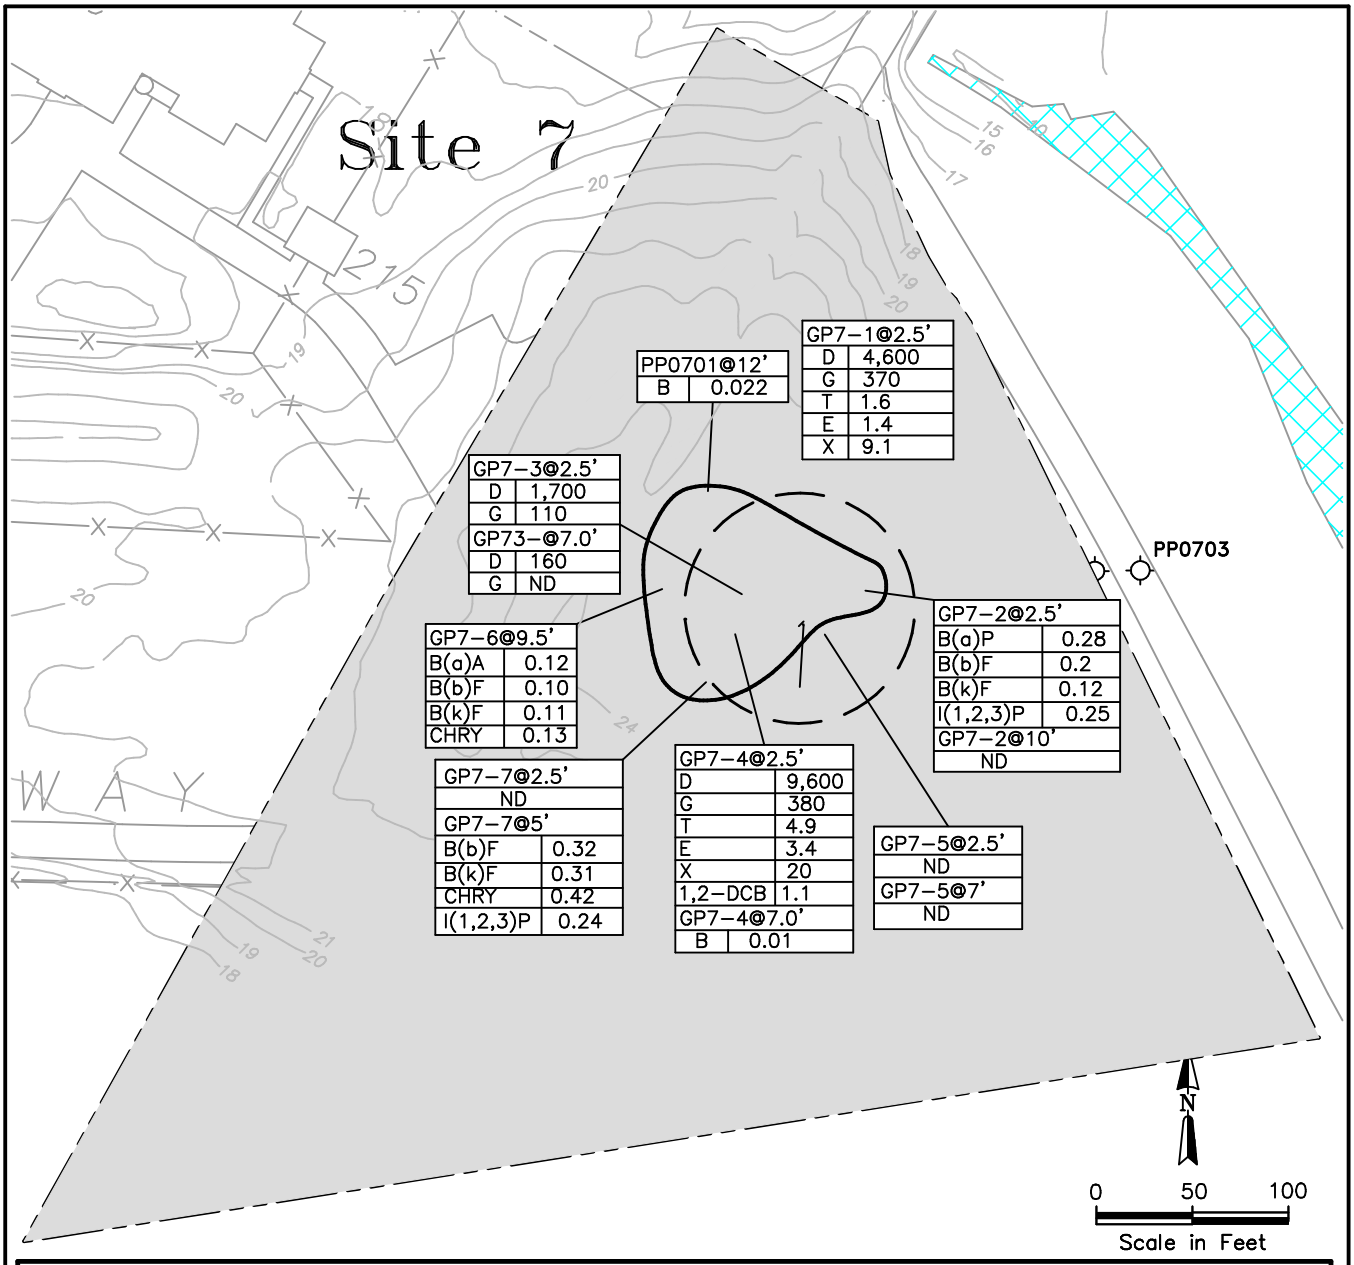
The former Burn Pit Area is situated southeast of Building 210 and for the most part, is located outside of the Portland ANGB boundary. The majority of IRP Site 7 lies on Port of Portland property.

3.7.1 Waste Disposal History

The burn pit was used for fire training exercises between 1957 and 1979. Several thousand gallons of flammable liquids, including waste oil, JP-4 jet fuel, and solvents, reportedly were burned each year in the pit (HMTC 1987). The former burn pit area has been filled with gravel and compacted.

3.7.2 Nature and Extent of Contamination

The results of soil gas and soil sampling conducted at IRP Site 7 indicate that petroleum-related VOCs including benzene, toluene, ethylbenzene, and xylenes (BTEX) are present above respective PSGs in the area of the former burn pit (Figure 3-13). Acetone was detected at concentrations ranging from 15 to 980 micrograms per kilogram in several Phase II RI soil samples. SVOCs and TPH as gasoline and diesel were also detected above PSGs in the area of the former burn pit (Figure 3-13). The lateral extent of soil contamination above PSGs is limited to the former burn pit area. Constituents detected above PSGs in shallow groundwater include benzene in direct-push samples PP0701 and GP7-10SZ, at concentrations of 1.7 µg/l and 2.97 µg/l, respectively, and PCE in a sample collected from monitoring well MW7-4 at a concentration of 2.0 µg/l in 1997. Additionally, TPH as diesel was detected in monitoring wells MW7-1 and MW7-3, and in three direct-push samples collected at the center and perimeter of the former burn pit. The cumulative analytical testing results for IRP Site 7 show that the constituents detected above PSGs are isolated detections rather than indicators of persistent groundwater contamination.



3.7.3 Risk Assessment Results

The results of the risk characterization for IRP Site 7 indicate the following:

- Both the estimated carcinogenic risks and the noncarcinogenic hazards are acceptable for Base workers, construction workers, reservists, hypothetical on-site residents, and by extension, off-site residents, under USEPA and ODEQ guidelines.

- Reported lead concentrations in soil were below the USEPA screening level for an unrestricted use scenario; thus lead in soil is not expected to pose an unacceptable risk.

Several groundwater samples in which PAHs were not detected were analyzed using detection limits greater than risk-based action levels, which may have underestimated associated risk. To verify the lack of risk associated with PAHs in groundwater at IRP Site 7, one round of groundwater samples will be collected and analyzed for PAHs using USEPA Method 8270-Selective Ion Monitoring (SIM) which will provide lower detection limits. This sampling is expected to occur during the second half of year 2001.

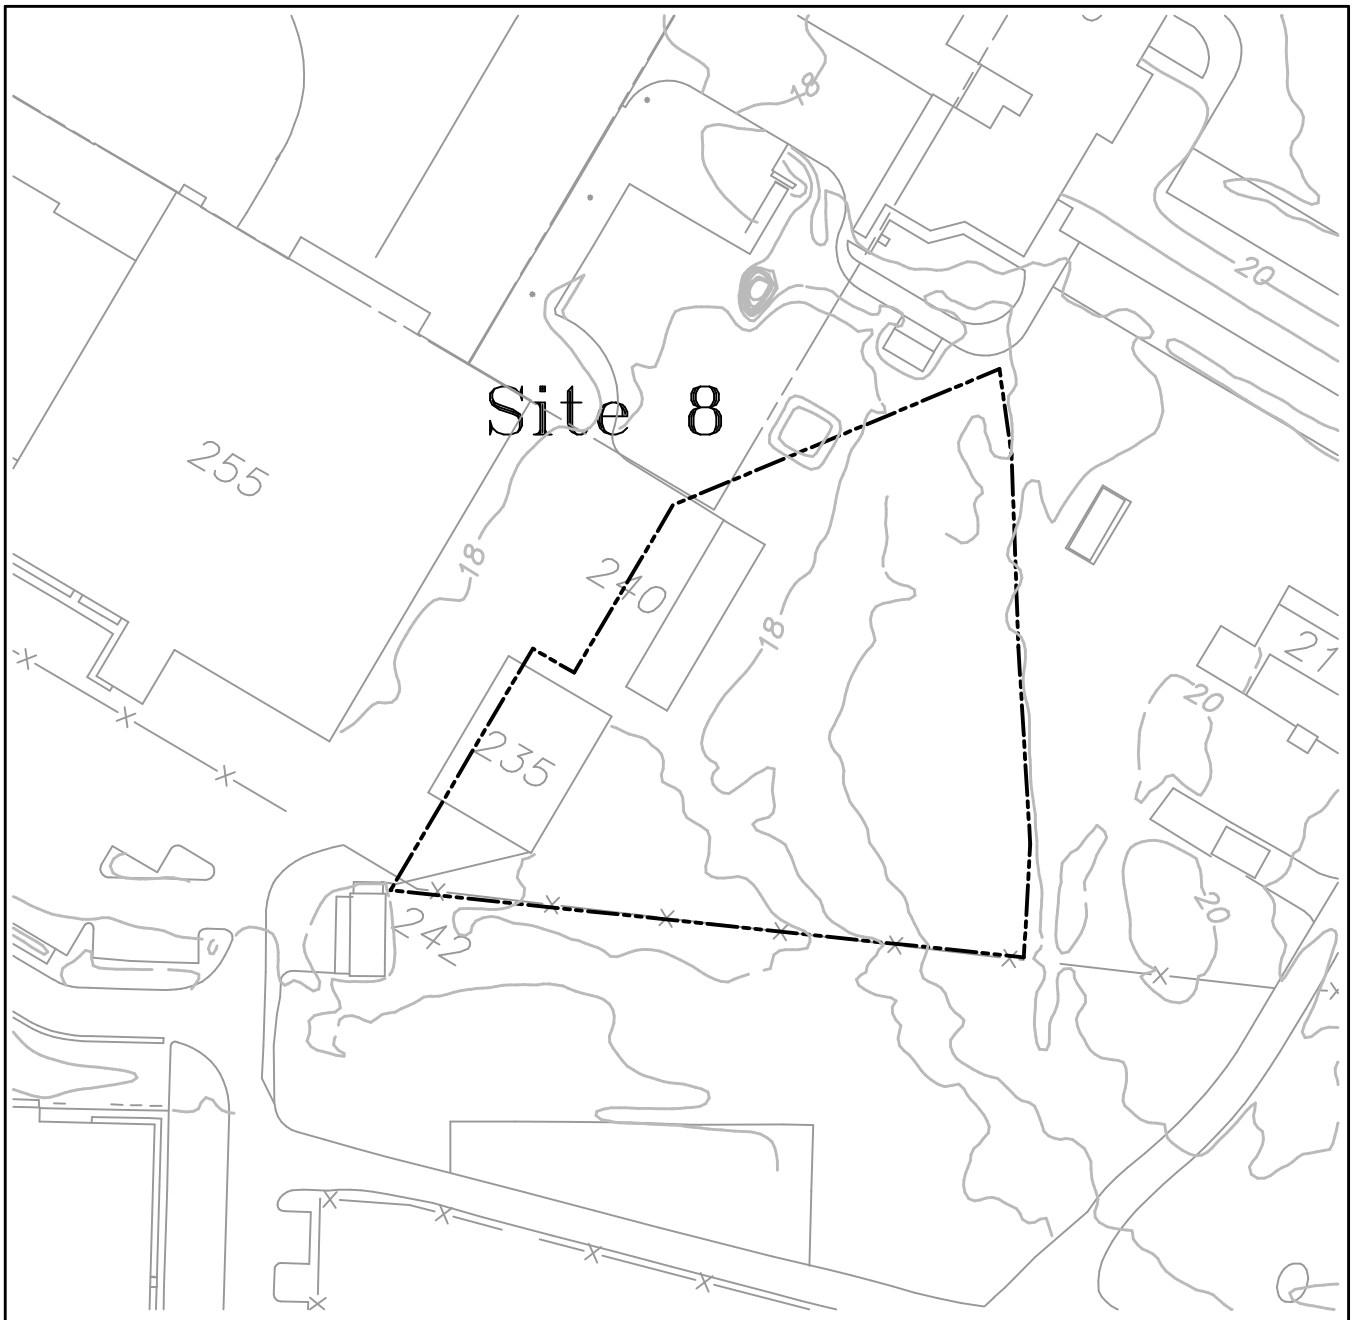
PORTLAND, OREGON

FIGURE 3–13

3.7.4 Recommendation

The constituents detected in groundwater at IRP Site 7 are isolated detections and do not indicate persistent groundwater contamination. The risk associated with these groundwater detections is acceptable based on all anticipated land and water use scenarios. It is recommended that no further remedial action be performed related to groundwater. It is also recommended that one round of groundwater samples be collected at IRP Site 7 and analyzed for PAHs using EPA Method 8270-SIM, as described in Section 3.7.3 above.



VOCs, SVOCs, and TPH as gasoline and diesel have been detected at concentrations greater than respective PSGs in soil samples collected from the area of the former burn pit. The soil contamination is limited to the area immediately surrounding the burn pit. The risks associated with soil at IRP Site 7 are acceptable based on an industrial land-use scenario. The use of this area is not expected to change in the future (City of Portland Bureau of Planning 2000a, 2000b). It is therefore recommended that no further action be performed related to soil.

3.8 IRP Site 8 - Sanitary Landfill

The former Sanitary Landfill is east of Building 255, and encompasses most of Building 235 and all of Building 240 (Figure 3-14). Reportedly, limited information is available to identify the exact location of past disposal activities at the Sanitary Landfill (HMTC 1987).

3.8.1 Waste Disposal History

The Sanitary Landfill was active between 1949 and 1956 and occupied an area of approximately 1 acre. Wastes were reportedly disposed of in trenches 6 to 8 feet deep, 60 to 70 feet long, 10 feet wide, and spaced 5 to 20 feet apart. Filled trenches were covered with 3 to 4 feet of excavated materials. The Sanitary Landfill received wastes generated by the Portland ANGB and the Army National Guard. The wastes consisted of ordinary shop and building refuse, paint cans, oil and paint residue, batteries, and broken equipment and parts (OpTech 1996).

IRP SITE 8
SANITARY LANDFILL

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 3-14

3.8.2 Nature and Extent of Contamination

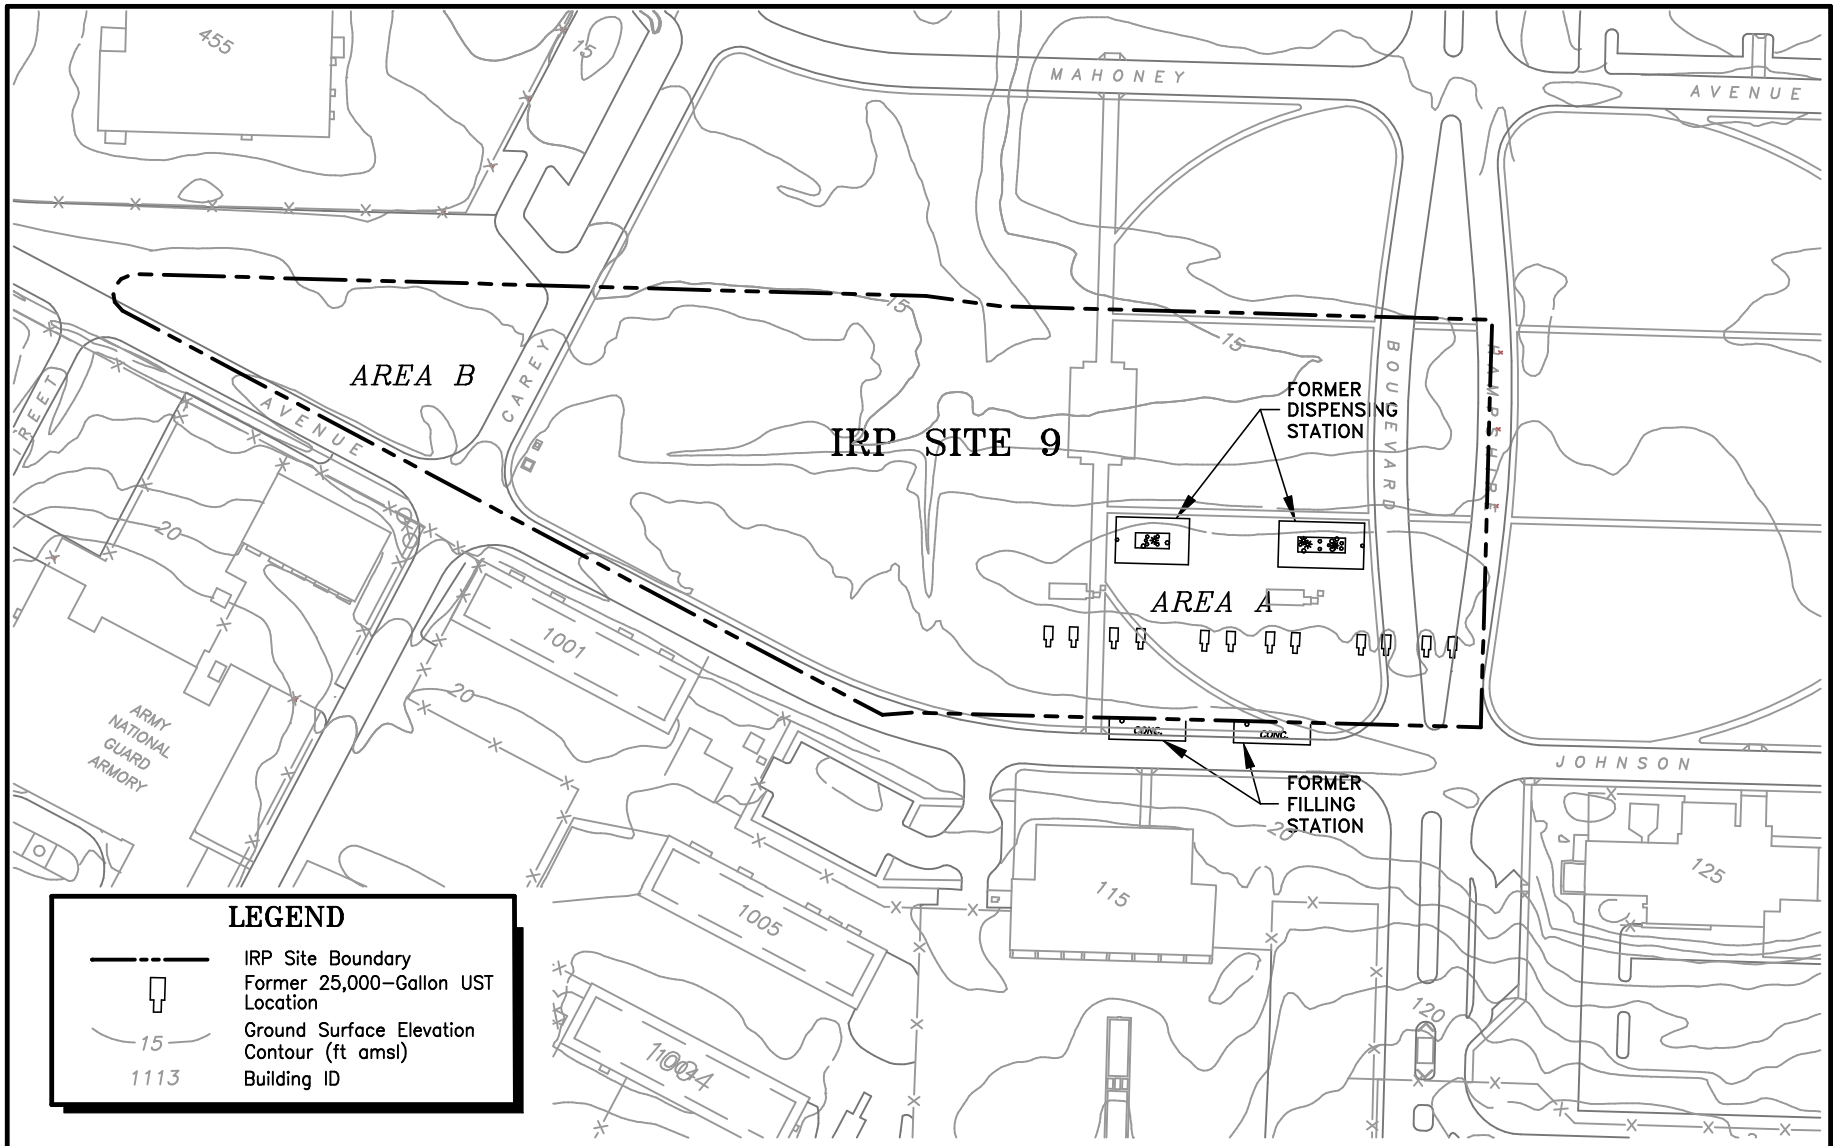
Three trenches were excavated through IRP Site 8 for underground utility construction following the SI. No evidence of landfilling was encountered. Evidence of landfilling also was not confirmed by an aerial photograph review performed during the SI.

Three direct-push groundwater samples were collected during the Phase I RI in an area downgradient of the subsurface anomalies identified by a ground-penetrating radar survey. These samples were analyzed for VOCs, SVOCs, PCBs, and metals. PCBs were not detected, and there were no confirmed detections of VOCs, SVOCs, or metals above applicable or relevant and appropriate requirements (ARARs). Reported detections of methylene chloride and bis(2-ethylhexyl)phthalate, both below 10 µg/l in one sample, are suspected laboratory artifacts.

Since landfilling activities were not confirmed and the Phase I RI sampling results indicated no adverse impacts to groundwater, IRP Site 8 was not investigated further.

3.8.3 Risk Assessment Results

The results of the risk characterization for IRP Site 8 indicate the following:



- No carcinogenic COCs were identified. The estimated non-carcinogenic hazards are acceptable for Base workers, construction workers, reservists, hypothetical on-site residents, and by extension, off-site residents, under USEPA and ODEQ guidelines.

3.8.4 Recommendation

No further action is recommended for IRP Site 8 due to the lack of confirmed detections of constituents above PSGs.

3.9 IRP Site 9 - Petroleum, Oil, and Lubricants Facility

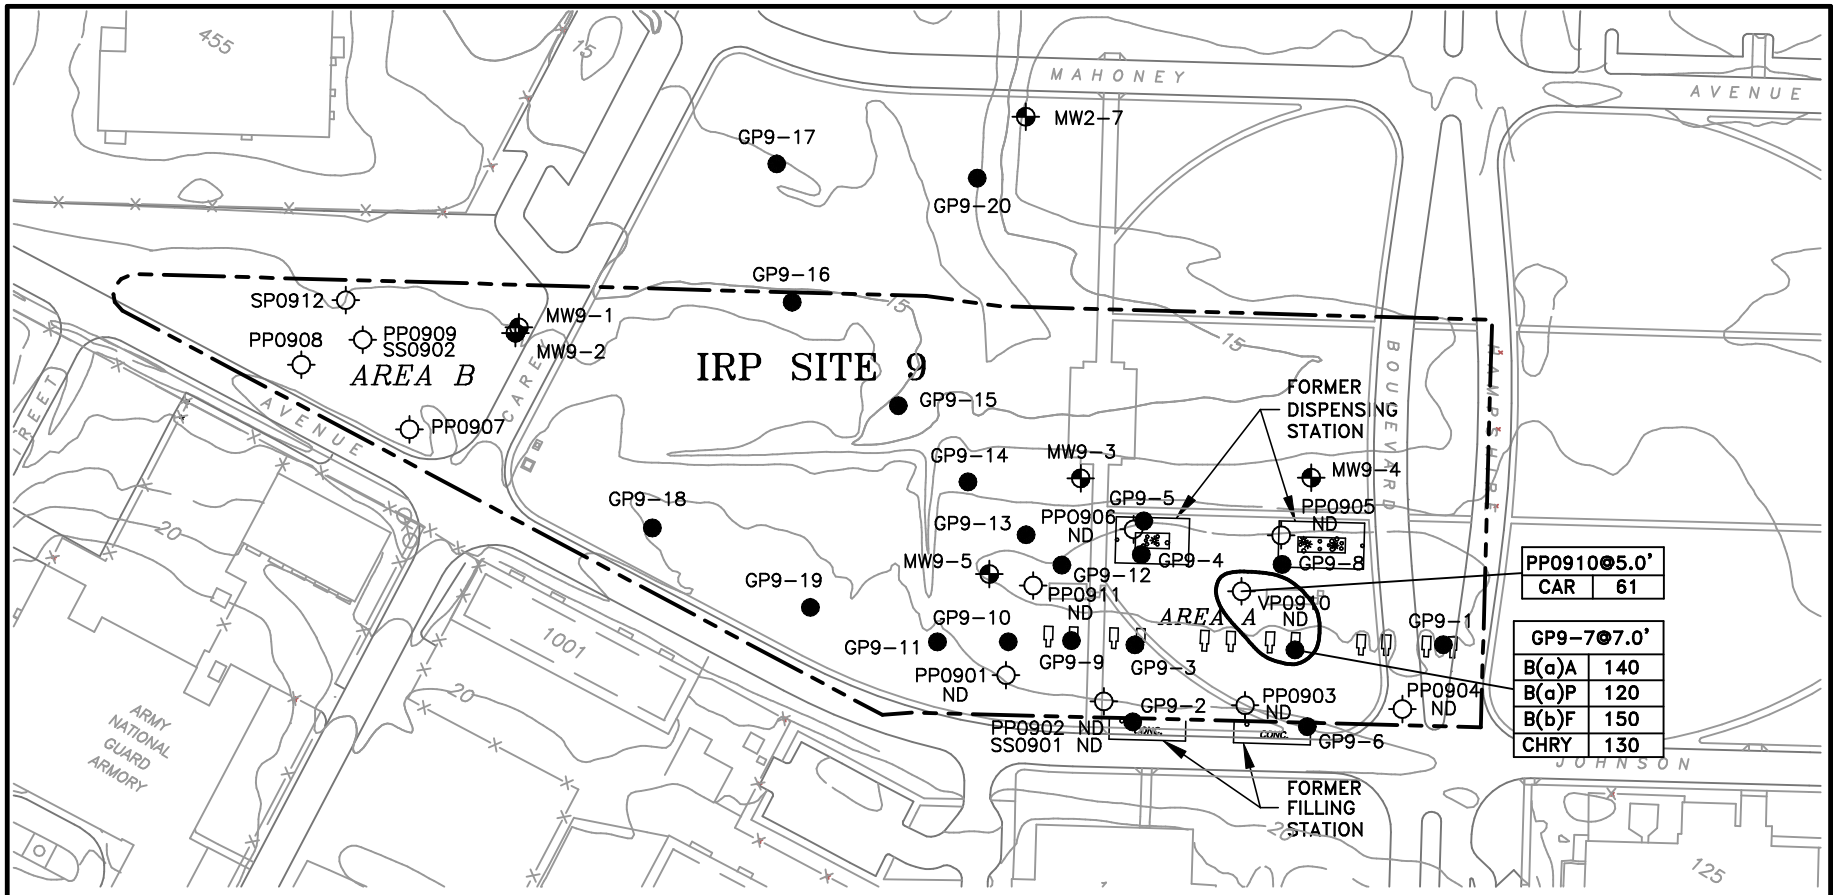
The former POL Facility is northwest of the intersection of Hampshire Boulevard and Johnson Avenue (Figure 3-15). Area A comprises the former main POL Facility, and two former fuel dispensing stations. Area B is the former diesel storage and dispensing area. Area A contained twelve 25,000-gallon USTs and one waste oil UST, which were all removed in

IRP SITE 9
FORMER PETROLEUM, OIL, AND LUBRICANTS STORAGE AREA
142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 3-15

March 1994. The scope and results of the UST removals are not well documented. Two aboveground storage tanks were also located at Area B (HMTC 1987).

The 25,000-gallon USTs at Area A were used to store JP-4 jet fuel. Refueler trucks were used to transfer fuel from IRP Site 9 to the flight apron area. Inventories and tightness test results did not indicate leaks in any of the tanks or associated piping.



3.9.1 Waste Disposal History

No waste disposal or storage activities are reported for IRP Site 9. During site construction activities in 1991, ANG personnel discovered TPH contamination in soils at Area A.

3.9.2 Nature and Extent of Contamination

TPH as gasoline and diesel were detected below respective PSGs in soil samples collected from Area A, as well as in samples collected from the area between Areas A and B (Figure 3-16). Groundwater samples collected at Area A were found to contain TPH as gasoline, diesel, and heavy oil; benzene, ethylbenzene, and xylenes; and petroleum-related polynuclear aromatic hydrocarbons (PAHs). Scattered detections of chlorinated VOCs also were observed in several direct-push groundwater samples collected at IRP Site 9. The benzene, ethylbenzene, and PAH concentrations in several groundwater samples exceeded respective PSGs. The distribution of TPH and BTEX in groundwater at IRP Site 9 is depicted on Figure 3-17. The extent of dissolved petroleum compounds in groundwater generally corresponds to the area of the highest TPH concentrations detected in soil. This correlation suggests that residual soil contamination in the vicinity of the former USTs may act as a continuing source of groundwater contamination. The PAHs are likely associated with the dissolved TPH, as there are no other known sources of these compounds at IRP Site 9.

Evidence of light non-aqueous phase liquid was not observed during the investigations at IRP Site 9. Although all of the groundwater monitoring wells are screened below the water table, the concentrations of TPH and BTEX detected in soil and groundwater at IRP Site 9 are significantly less than the concentrations typically observed at non-aqueous phase liquid sites.

PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 3–17

G:\CAD\DWGS\6049\71
60497135.dwg, 01/03/01

Sporadic detections of TCE; cis-1,2-DCE; and VC were observed in several groundwater samples. These compounds were not detected in any of the soil samples, and there are no known sources of chlorinated VOCs at IRP Site 9.

Buried utilities are present at IRP Site 9. These utilities may provide a preferential pathway for VOC vapors to travel a small distance away from the source of those vapors. If deep enough, the utility channels may also allow groundwater to flow a short distance away from the general flow path. However, utilities would need to be buried within the Shallow Zone (below approximately 12 feet bgs) to have any effect on groundwater or contaminant flow direction. Remedial action at this site will require consideration of the presence of buried utilities.

3.9.3 Risk Assessment Results

The results of the risk characterization for IRP Site 9 indicate the following:

- Both the estimated carcinogenic risks and the noncarcinogenic hazards are acceptable for Base workers, construction workers, and reservists under USEPA and ODEQ guidelines.

- The total estimated carcinogenic risk for hypothetical on-site residents exceeds USEPA and ODEQ acceptable levels, primarily as a result of assumed exposures to benzene and PAHs in groundwater under this scenario. Additionally, the carcinogenic risk associated with benzo(a)pyrene in soil under the on-site residential scenario exceeds the ODEQ benchmark for acceptable risk associated with an individual constituent. The noncarcinogenic hazard for hypothetical on-site residents also exceeds both USEPA and ODEQ guidelines, primarily as a result of benzene in groundwater. By extension of the results for the on-site residential scenario, the potential future risks to off-site residents related to the possible off-site migration and residential use of contaminated groundwater also exceed USEPA and ODEQ criteria.

Reported lead concentrations in soil were below the USEPA screening level for an unrestricted-use scenario; thus lead in soil is not expected to pose an unacceptable risk.

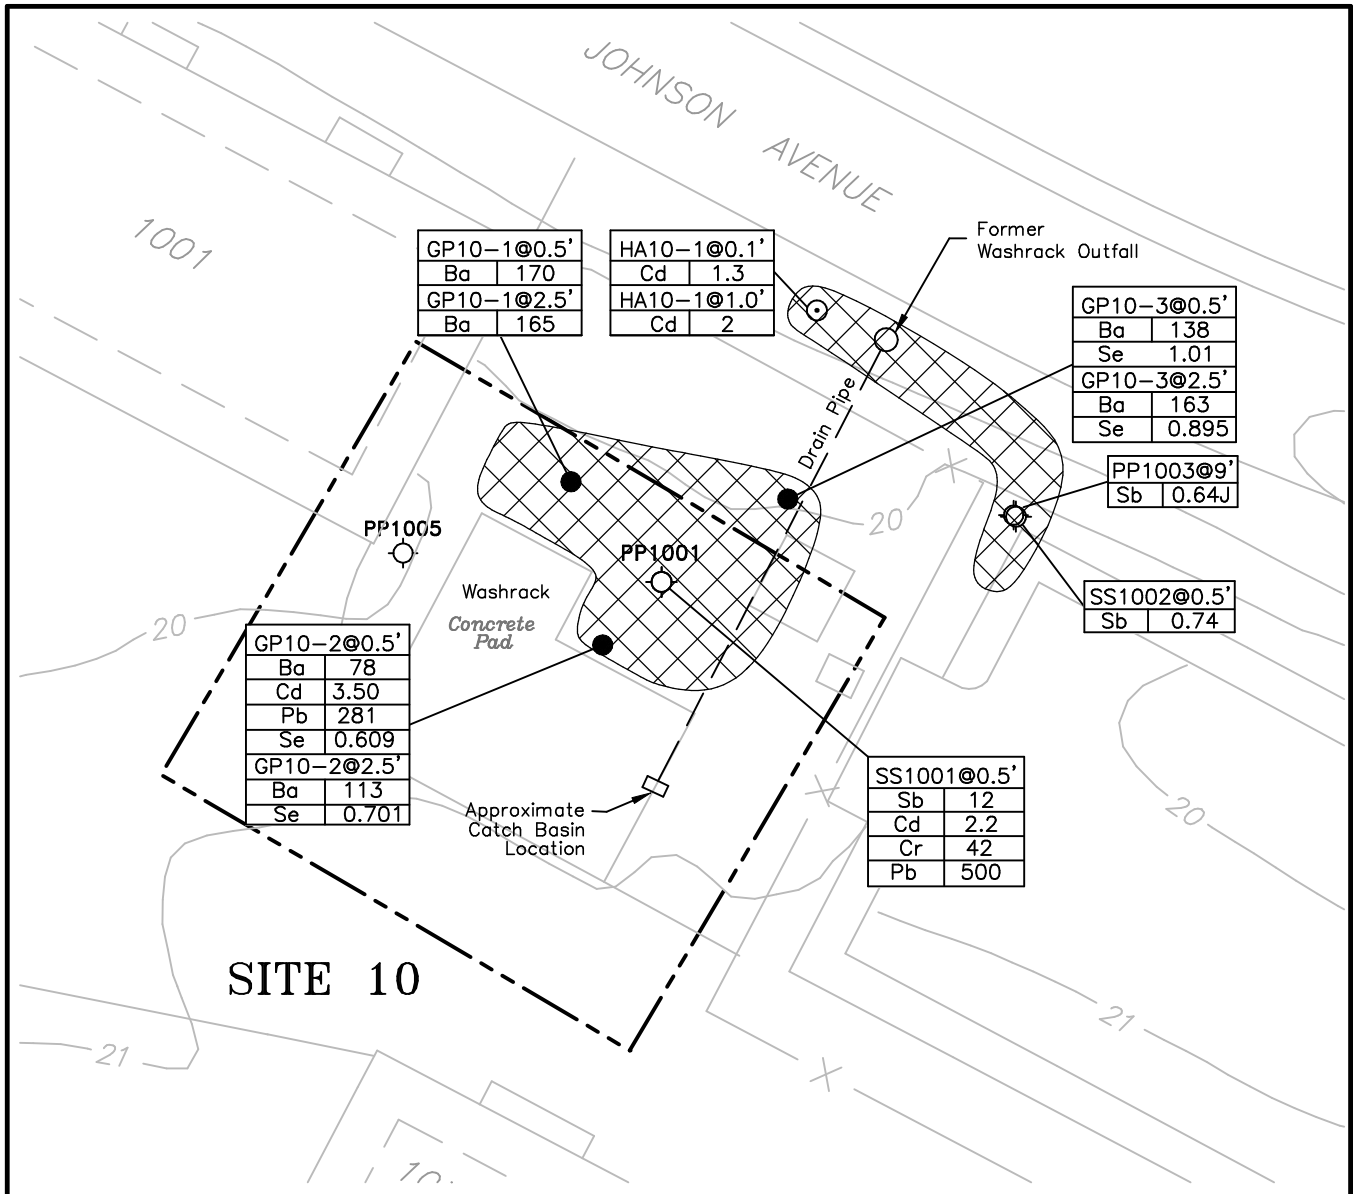
3.9.4 Recommendation

SVOCs have been detected at concentrations greater than PSGs in soil samples collected at IRP Site 9. However, the risks associated with soil at IRP Site 9 are acceptable based on an industrial land-use scenario. The industrial land use of this area is not expected to change in the future (City of Portland Bureau of Planning 2000a, 2000b). It is therefore recommended that no further action be performed related to soil.

It is recommended that remedial alternatives be developed that address TPH and BTEX compounds remaining in IRP Site 9 groundwater. The development of these alternatives is discussed in Sections 4.0 and 5.0.

3.10 IRP Site 10 - Equipment Washrack

The Equipment Washrack is at the southeast corner of Building 1001 (Figure 3-18). The washrack consists of an irregularly shaped concrete pad, approximately 45 feet long by 30 feet wide; a catch basin; and a drain pipe.



3.10.1 Waste Disposal History

The washrack was installed in 1950 and used until 1993. The concrete pad slopes toward the east to a catch basin that collected wash fluids from equipment and vehicle-cleaning activities. The wash fluids discharged via the drain pipe to a roadside ditch along Johnson Avenue, northeast of the washrack area.

3.10.2 Nature and Extent of Contamination

TPH was detected below PSGs in two surface soil samples collected from the former drainage ditch north of Site 10 during the RI. The presence of petroleum compounds detected above PSGs in soil in 1993 was not confirmed by the RI sampling, suggesting that the elevated concentrations are very limited in extent and/or have attenuated.

As shown on Figure 3-18, antimony, cadmium, lead, and/or selenium were detected above respective PSGs in soil samples collected from five locations. The concentrations of antimony detected in surface soil sample SS1002 and in the subsurface sample collected from boring PP1003 (0.74 and 0.64 mg/kg, respectively) are not significantly higher than the

PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 3–18

Portland ANGB background level of 0.59 mg/kg; these antimony detections likely reflect background conditions.

A site-specific background value for selenium is not available for comparison with the RI soil sampling results. However, the selenium results also appear to reflect background conditions, as indicated by the consistent selenium concentrations in the RI samples, and the absence of cadmium and lead concentrations above respective PSGs in the majority of samples with selenium detections above PSGs.

Concentrations of antimony, cadmium, and lead detected in surface soil sample SS1001 are elevated relative to Portland ANGB background levels.

Similarly, cadmium concentrations in the samples collected from boring HA10-1, and cadmium and lead concentrations detected in the sample collected from 0.5 feet bgs in boring GP10-2, appear to be elevated relative to background. These elevated metal concentrations may be related to past equipment and vehicle washing activities at IRP Site 10. The elevated metal concentrations at these locations are limited to the uppermost 1 to 2.5 feet of soil.

The results of direct-push groundwater sampling indicate that groundwater quality at IRP Site 10 has not been adversely impacted by past site activities.

3.10.3 Risk Assessment Results

The results of the risk characterization for IRP Site 10 indicate the following:

- Both the estimated carcinogenic risks and the noncarcinogenic hazards are acceptable for Base workers, construction workers, reservists, hypothetical on-site residents, and by extension, off-site residents, under USEPA and ODEQ guidelines.

- With one exception, reported lead concentrations in soil were below the USEPA screening level of 400 mg/kg for an unrestricted-use scenario. Lead was detected in one sample at a concentration of 500 mg/kg, which is below the USEPA screening level of 750 mg/kg for an industrial-use scenario.

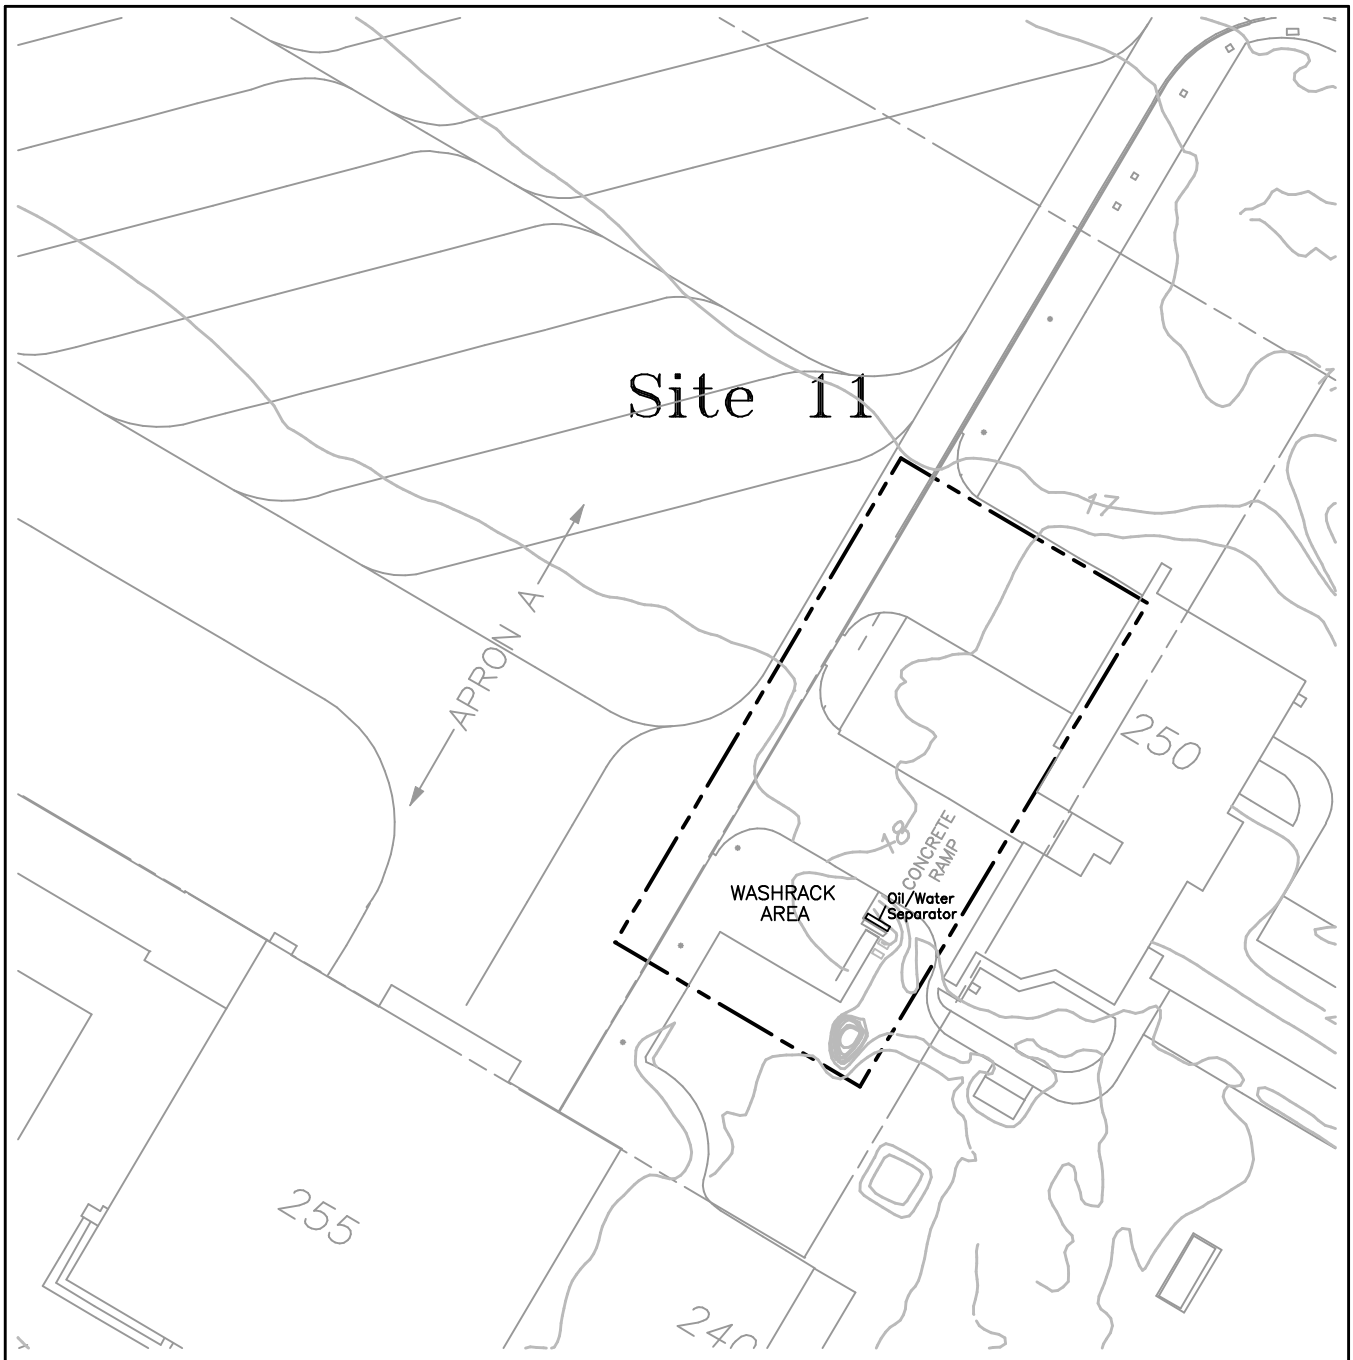
3.10.4 Recommendation

The results of the RI indicate that groundwater quality at IRP Site 10 has not been adversely impacted by past site activities. Therefore, it is recommended that no further action be performed related to groundwater.

Metals have been detected at concentrations greater than respective PSGs in soil samples collected at IRP Site 10. However, the risks associated with soil are acceptable based on an industrial land-use scenario. It is not expected that the use of this area will change in the future. It is therefore recommended that no further action be performed related to soil.

3.11 IRP Site 11 - Washrack West of Building 250

The former Washrack West of Building 250 is at the southeast corner of Apron A, adjacent to Building 250 (Figure 3-19), and was used to wash aircraft. The washrack facility consisted of a 60-foot by 80-foot pad, and an oil/water separator. The concrete pad sloped toward the east, where surface runoff from the pad drained to the oil/water separator. Solvents and degreasers were sometimes applied to the aircraft before washing them with a soap and water mixture. The washrack and oil/water separator were removed in September 1999 as part of a soil removal action (ERM 2000b). Contaminated soil was hauled off-site and treated by thermal desorption.



3.11.1 Waste Disposal History

Liquids from aircraft washing operations flowed from the washrack area to the catch basin of the oil/water separator. The oil/water separator discharged into the storm sewer prior to 1984, and into the sanitary sewer after 1984.

The oil/water separator was a three-stage, concrete, gravity-type separator, which was removed from service in 1989 after cracks were discovered in the center stage.

3.11.2 Nature and Extent of Contamination

Contaminants detected in soil and groundwater at IRP Site 11 include chlorinated VOCs, BTEX, TPH, and metals. The lateral extent of VOCs and TPH in soil prior to the 1999 removal action was generally limited to

ERM

G:\\6049\71

PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 3-19

within 25 feet of the oil/water separator. Figure 3-20 shows the extent of organic contaminants remaining in soil after the 1999 removal action; VOCs and TPH are still present above respective PSGs in soil near the water table.

VOCs and petroleum hydrocarbons have impacted groundwater in the Shallow Zone and Deep Zone at IRP Site 11. The extent of chlorinated VOCs in groundwater is shown on Figure 3-21. VOCs have migrated primarily toward the northwest from the area of the former separator, and have also dispersed radially. The concentrations of chlorinated VOCs have fluctuated since regular groundwater monitoring began in 1997. The fluctuating concentrations most likely reflect seasonal changes in groundwater levels and flow directions.

Deep Zone wells/piezometers in the vicinity of Site 11 include EW11-1, PZ11-1, PZ11-3, MW11-2, MW11-8, and MW11-12. Benzene; toluene; 1,2-DCA; cis-1,2-DCE; and VC were detected above respective PSGs in groundwater samples collected from well MW11-2. Additionally, VC was detected above the PSG in piezometer PZ11-3, and cis-1,2-DCE was detected below the PSG in well MW11-12. These detections indicate that dissolved VOCs have migrated to the Deep Zone northwest and southeast of the former oil/water separator. Figure 3-22 shows the vertical distribution of total chlorinated hydrocarbons at IRP Site 11.

CRSA wells/piezometers in the vicinity of IRP Site 11 include EW11-2, PZ11-2, PZ11-4, PZ11-5, and MWBG-11. There have been no confirmed detections of contaminants in these wells/piezometers.

During the Phase II RI, two direct-push groundwater samples (GP11-5 and GP11-6) were collected from the bottom of the Shallow Zone to assess the potential presence of dense non-aqueous phase liquid (DNAPL) in the immediate vicinity of the oil/water separator. Although dissolved VOCs were detected in these groundwater samples, the concentrations were not indicative of DNAPL; the maximum VOC concentration detected was 63 µg/l (VC). Concentrations on the order of 10,000 µg/l indicate the possible presence of DNAPL (Pankow and Cherry 1996).

3.11.3 Risk Assessment Results

The results of the risk characterization for IRP Site 11 indicate the

following:

- Both the estimated carcinogenic risks and the noncarcinogenic hazards are acceptable for Base workers, construction workers, and reservists under USEPA and ODEQ guidelines.

- The potential carcinogenic risk and noncarcinogenic hazard associated with soil exposures under the on-site residential land-use scenario are less than USEPA and ODEQ guidelines for evaluation of acceptable risk. However, the total carcinogenic risk and noncarcinogenic hazard for hypothetical on-site residents exceed both USEPA and ODEQ levels of acceptable risk, as a result of assumed exposures to groundwater under this scenario. The unacceptable risks are associated with the presence of benzene; 1,2-DCA; and VC in groundwater. In addition, the presence of cis-1,2-DCE in both soil and groundwater results in a cumulative hazard index (HI) for this contaminant that exceeds USEPA and ODEQ guidelines. By extension of the results for the on-site residential scenario, the potential future risks to off-site residents related to the possible off-site migration and residential use of contaminated groundwater also exceed USEPA and ODEQ criteria.

- Reported lead concentrations in soil were below the USEPA screening level for an unrestricted-use scenario, thus lead in soil is not expected to pose an unacceptable risk.

3.11.4 Recommendation

Due to the extent and concentrations of VOCs in groundwater at IRP Site 11, remediation is necessary to prevent possible off-site migration and residential use of the contaminated groundwater. Remedial alternatives have been developed and are presented later in this FS for the treatment of groundwater contaminated with VOCs.

Contaminated soil remaining at the excavation limits of the 1999 soil removal action should also be remediated, to prevent potential leaching of contaminants to groundwater. During the 1999 soil removal action, soil vapor extraction (SVE) piping was installed in the imported excavation backfill material. SVE removes VOCs and TPH through volatilization and enhanced aerobic bioremediation. The SVE system at Site 11 should be completed and placed in operation to treat the contaminated soil.

In order to begin a non-time critical removal action of VOCs in groundwater, the groundwater EE/CA described in Section 2.8.1 was initiated at IRP Site 11 (ERM 2001b). The groundwater EE/CA is currently being designed and is expected to be constructed during the year 2002. The purpose of the EE/CA is to remove a large amount of VOC mass from Shallow Zone groundwater in order to stop or slow migration of VOCs to downgradient areas of Shallow Zone groundwater and to Deep Zone groundwater. The design focuses on the central area of the Shallow Zone VOC plume, where concentrations of VC and cis-1,2-DCE, the primary contaminants of concern at IRP Site 11, are above approximately 100 µg/l. In addition to treatment of Shallow Zone groundwater at IRP Site 11, the EE/CA also presents a plan to remediate the area of contaminated soil remaining following the 1999 soil removal action described above. This remedial action will consist of completing and activating the SVE system, as mentioned, as well as injecting an oxygen releasing material into the vadose zone soil that becomes saturated during the wetter months. Although a significant reduction of VOCs is expected during the groundwater EE/CA implementation, a conservative position is taken in this FS by not considering this reduction during the development and evaluation of the remedial alternatives presented later in the document.

SECTION 4.0

DEVELOPMENT OF REMEDIAL ALTERNATIVES

In the preceding section (Section 3.0, Description of IRP sites), each of the IRP sites at the Portland ANGB was described with respect to the site history, nature and extent of contamination, the environmental and human health risk, and a recommendation for RA. As described in Section 3.0, IRP Sites 2, 9, and 11 are recommended for further evaluation of RA.

In this section, the proposed remedial alternatives are identified and the process by which the proposed remedies were developed and evaluated, based on USEPA (USEPA 1988) and ODEQ (ODEQ 1998b) guidance, is presented. The remedial alternatives will be compared and evaluated further in Section 5.0, which presents the preferred remedial alternatives proposed for the IRP sites.

The process of identifying RA alternatives for IRP Sites 2, 9, and 11 involves the following primary steps:

- **Identification of ARARs**: "Applicable" requirements are substantive environmental protection requirements specifically addressing a hazardous substance, pollutant, contaminant, activity, location, or other circumstance at a site. "Relevant and appropriate" requirements are those that, while not applicable, are sufficiently similar to circumstances encountered at a site that their use is well suited.

- **Development of RAOs**: RAOs provide specific goals for each of the affected media (i.e., soil, groundwater, etc.) at the IRP sites requiring remediation. These goals are typically based on achievement of a specified clean-up level, or specified acceptable risk level.

- **Development of General Response Actions**: General response actions are broadly defined as measures designed to prevent or minimize the adverse environmental impacts to satisfy the RAOs.

- **Identification and Screening of Technologies**: Once general response actions are identified, technologies that are capable of achieving the RAOs are identified, and subsequently "screened" to provide a short list of technologies appropriate for further consideration.

- **Development of Remedial Alternatives**: Using the RAOs, general response actions, and technologies known to be applicable to the COCs, remedial alternatives are then developed for comparison and further evaluation relative to the USEPA and ODEQ criteria.

4.1 ARARs

Section 121 of Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) requires RAs to comply with all ARARs formally promulgated under Federal and State environmental laws. "Applicable" requirements are substantive environmental protection requirements specifically addressing a hazardous substance, pollutant, contaminant, RA, location, or other circumstance at a site. "Relevant and appropriate" requirements are those that, while not applicable, are sufficiently similar to circumstances encountered at a site that their use is well suited. Administrative requirements, such as Federal, State, or local permitting, for RAs completed entirely on-site are waived under CERCLA Section 121(e)(1).

There are three types of ARARs:

- Location-specific ARARs are restrictions imposed on activities or concentrations of hazardous substances solely because they occur in special locations.

- Chemical-specific ARARs are health- or risk-based criteria that establish the acceptable amount or concentration of a chemical that may be found in or discharged to the ambient environment.

- Action-specific ARARs set controls or restrictions on design and performance aspects of activities at the site.

ARARs are progressively identified on a site-specific basis as the RI/FS proceeds. During the RI, confirmation of contamination at a site, identification of the specific contaminant(s), and subsequent laboratory analysis and quantification allow for the determination of chemical-specific ARARs. These chemical-specific ARARs, along with chemical-specific guidance "to be considered," are identified in this section, along with action- and location-specific ARARs identified as part of the FS process.

4.1.1 Federal Applicable or Relevant and Appropriate Requirements

4.1.1.1 Safe Drinking Water Act

Federal regulations pursuant to the Safe Drinking Water Act govern the quality of groundwater that is or could be used for drinking water purposes. Safe Drinking Water Act MCLs specified in Title 40, Part 141, Sections 11 to 16 of the Code of Federal Regulations are chemical-specific ARARs for groundwater at the Portland ANGB. MCLs for the constituents identified at the Portland ANGB are listed in Tables 4-1 and 4-2.

4.1.1.2 Clean Water Act

The Federal Clean Water Act and pursuant regulations provide potential location-, chemical-, and action-specific ARARs, such as water quality standards and wastewater discharge requirements. RAs that involve discharge to surface water will require compliance with the substantive requirements of the Clean Water Act.

4.1.1.3 Clean Air Act

The Federal Clean Air Act provides potential action- and chemical-specific ARARs for IRP activities that may release contaminants to the atmosphere. RAs that involve discharge of contaminants, particularly VOCs, to the atmosphere will require compliance with the substantive requirements of the Clean Air Act.

4.1.1.4 Resource Conservation and Recovery Act

Federal Resource Conservation and Recovery Act (RCRA) regulations contain requirements that apply to the generation, management, and disposal of hazardous waste. Based on the *Listed Hazardous Waste Evaluation* (ERM 1999c) prepared by ERM, contaminated media containing TCE and degradation product chlorinated VOCs at IRP Sites 1, 2, 3, 4, and 5 meet the criteria for hazardous waste under RCRA. Soil, sediment, surface water, and groundwater waste containing TCE and generated from these sites should be managed as hazardous waste. Hazardous waste generation, storage, and transport requirements under RCRA are applicable to these materials.

(1) Oregon rules state that GRCs are not to be used as an ARAR for site cleanups conducted under CERCLA. They are included here for comparison purposes only.
(2) PRG listed is for Chromium VI; no tap water PRG exists for total chromium.
(3) PRG listed is for methyl mercury; no tap water PRG exists for elemental mercury.
(4) PRG listed is for thallium chloride; no tap water PRG exists for total thallium.

4.1.2 Federal Guidance to be Considered

In addition to Federal and State requirements that may be ARARs for IRP activities, Federal nonregulatory criteria must be considered. Chemical-specific Federal nonregulatory criteria that may be used to help characterize risks and to set cleanup goals include the USEPA Region 9 preliminary remediation goals (PRGs).

USEPA Region 9 PRGs (USEPA Region 9 2000) are risk-based preliminary screening levels that are used to assess potential concerns related to chemical occurrence defined during previous and ongoing investigations. The PRGs are generally used to eliminate sites of interest that are not of concern with regard to human health risk. The PRGs developed by the USEPA Region 9 for carcinogenic substances correspond to an excess lifetime cancer risk of 1×10^{-6}; the PRGs for noncarcinogenic substances correspond to a HI of 1.

4.1.3 State Applicable or Relevant and Appropriate Requirements

The State of Oregon laws governing cleanup of contaminated sites are outlined in Oregon Revised Statute 465. Environmental Cleanup Rules developed in support of the Oregon Revised Statute laws are included in the OAR 340-122. OAR 340-122 outlines cleanup requirements to ensure the protection of human health and the environment while allowing flexibility in site-specific application of these requirements. OAR 340-122 defines a three-step approach for establishing cleanup requirements for individual sites: (1) determining human and ecological exposure pathways of concern for contaminants, (2) establishing appropriate cleanup standards, and (3) selecting cleanup actions that would best achieve the cleanup standards.

OAR 340-122 provides a number of options for establishing site-specific cleanup levels. Each of these options uses human health risk as the main determinant in setting cleanup levels. The options outlined in OAR 340-122 are described in the sections below. In addition, ODEQ requires that PRGs established by the USEPA Region 9 be reviewed as potential screening-level concentrations. Potential State of Oregon ARARs for soil and groundwater at the Portland ANGB, and the soil screening levels from the USEPA Region 9 PRG tables, are presented in Tables 4-1 through 4-5.

4.1.3.1 Oregon Soil Matrix Cleanup Levels

Oregon Soil Matrix Cleanup Levels (OAR 340-122-315 through 335) apply to soil remediation of petroleum releases from UST systems at relatively simple sites. Individual sites are evaluated by assigning a numerical score for each of the following parameters: (1) depth to groundwater, (2) mean annual precipitation, (3) native soil or rock type, (4) sensitivity of uppermost aquifer, and (5) potential receptors (water supply wells). Total scores for each site determine which of three cleanup levels for gasoline-range hydrocarbons (40, 80, or 130 mg/kg) and diesel-range hydrocarbons (100, 500, or 1,000 mg/kg) apply.

4.1.3.2 Oregon Soil Cleanup Levels

Oregon rules specifically indicate that the Oregon Soil Cleanup Levels (SCLs) are not to be used as an ARAR for site cleanups conducted under CERCLA. However, they are discussed here for completeness and comparison to other chemical-specific ARARs and screening levels.

Oregon SCLs (OAR 340-122-045) comprise Maximum Allowable Soil Concentrations (MASCs) for remediation of 64 common organic compounds for sites where contaminant leaching to groundwater is a concern. SCLs for compounds identified at the Portland ANGB are included in Table 4-4. Oregon SCL concentrations were developed based on human health risk; OAR 340-122-045(3)(a) states that at sites with multiple contaminants, these cleanup levels may be prorated downward to keep health risks below targeted levels.

4.1.3.3 Groundwater Reference Concentrations

Oregon rules indicate that the Groundwater Reference Concentrations (GRCs) are not to be used as an ARAR for site cleanups conducted under CERCLA. However, they are discussed for completeness and comparison to other chemical-specific ARARs and screening levels.

GRCs are presented in the OARs for the purpose of establishing alternative soil cleanup levels under OAR 340-122-045. They were developed as maximum allowable groundwater concentrations for 64 organic compounds, 11 metals, and cyanide. GRCs for constituents identified at the Portland ANGB are included in Tables 4-1 and 4-2. If an Oregon GRC is not available for a particular contaminant, the ODEQ

generally accepts the Federal MCL or Secondary Maximum Contaminant Level for the contaminant. If an MCL or Secondary Maximum Contaminant Level is not available for the contaminant, ODEQ generally accepts concentrations that are protective of human health to an excess cancer risk level of 1×10^{-6}.

4.1.3.4 Maximum Allowable Soil Concentrations

MASCs (OAR 340-122-045) were developed for sites where groundwater impacts are not a concern. Oregon has developed residential and industrial MASCs. MASCs for constituents identified at the Portland ANGB are listed in Tables 4-4 and 4-5.

4.1.3.5 Oregon Air Pollution Control Requirements

Air emissions from site RAs are regulated under two State requirements: *Notice of Construction and Approval Plans* (OAR 340-028-800 to 820), and *Rules Applicable to Sources Required to Have Air Contaminant Discharge Permits* (OAR 340-028-0600). Of these regulations, the only potentially substantive air pollution control requirement that could be considered an ARAR for the possible RAs at the Portland ANGB is contained in OAR 340-028-0600(1) which states that degradation of existing air quality by new contamination sources shall be minimized to the greatest extent possible.

Compliance with OAR 340-028-0600(1) is defined as compliance with emission requirements in the ODEQ's Hazardous Air Pollutant regulations (OAR 340-032-0105 through 0130). Rates of VOC emissions from the anticipated RAs would be far lower than *de minimis* rates specified in OAR 340-032-0130. Therefore, anticipated RAs are expected to be in compliance with the anti-degradation provision in OAR 340-028-0600(1).

4.1.3.6 Underground Injection Well Requirements

A well or boring used for the purpose of injecting a remediation fluid is classified as a Class V Injection Well by ODEQ. The ODEQ requires submittal of an Underground Injection Control (UIC) Registration for Aquifer Remediation Systems for RAs where fluids will be injected into the subsurface (e.g., in situ chemical oxidation). In addition to registering injection wells, ODEQ has emphasized several requirements that must be

met during remediation using underground injection. The primary components of these requirements are:

- The Air National Guard (ANG) must provide public notice (published in local newspaper and mailers sent to interested parties) and a 30-day opportunity to comment on any proposed injection activities. A public meeting must be held to receive comments if requested by 10 or more persons or by a group with a membership of 10 or more.

- No activities shall be conducted that exacerbate existing groundwater contamination or that could cause an adverse impact on existing or potential beneficial uses of groundwater.

- Activities must include an adequate monitoring and reporting program that will allow the public to confirm that the activities are not having an adverse impact.

4.1.4 Wastewater Discharge Requirements

Non-hazardous wastewater generated during RAs will require testing to ensure compliance with the limits set by the City of Portland Bureau of Environmental Services, the operator of the publicly-owned treatment works (POTW) to which the wastewater will be discharged. Wastewater in compliance with these limits may be discharged to the POTW under the existing Portland ANGB discharge permit. If necessary, the water will be treated prior to discharge so that it complied with the POTW limits.

4.2 Remedial Action Objectives

This section presents the development of RAOs for IRP Sites 2, 9, and 11. The RAOs provide media and contaminant-specific (i.e., specific to soil, groundwater, etc.) goals for protecting human health and the environment. The RAOs specify:

- The media and COCs;

- Exposure routes and receptors; and

- Clean-up levels (i.e. acceptable contaminant levels) and applicable criteria.

These criteria are discussed in more detail below:

Media and Contaminants of Concern. The medium of concern for evaluation in the FS is groundwater at IRP Sites 2, 9, and 11. Shallow Zone groundwater is a medium of concern at all three mentioned sites. Deep Zone groundwater is also a media of concern at IRP Sites 2 and 11.

The COCs in groundwater at the Portland ANGB are VOCs. For the purpose of simplifying the discussion of several COCs, the COCs used for this FS were limited to the four most commonly detected compounds: benzene, TCE, cis-1,2-DCE, and VC. These compounds were chosen based on their frequency and distribution of detections above respective PSGs relative to other VOCs detected at the Base. Several other VOCs have been detected at the Base above their PSGs but these detections have either been sporadic and less predictable or have consistently occurred along with detections of the more common VOCs mentioned above.

Specifically, TCE; cis-1,2-DCE; and VC are the COCs at IRP Site 2. Benzene is the COC for IRP Site 9, and cis-1,2-DCE and VC will be used at IRP Site 11.

VC is the primary contaminant of concern in Deep Zone groundwater at IRP Sites 2 and 11. Other VOCs have been detected in samples from Deep Zone monitoring wells at these sites, but not at concentrations significantly higher than the PSGs, as is the case with VC.

Exposure Routes and Receptors. There are several potential exposure pathways for groundwater at the Portland ANGB. As discussed in the beneficial-use survey presented in Section 2.0, some potential pathways correspond with direct exposure to groundwater contaminants, such as ingestion of drinking water or aquatic life exposure via groundwater discharge to surface water. Other pathways involve indirect exposure to groundwater or contaminants in groundwater, such as exposure by indoor air inhalation.

The indoor air inhalation pathway was explored due to the presence of buildings near areas with chemically impacted groundwater. Based on the industrial use of such buildings and on methods developed by the American Society for Testing and Materials (ASTM), risk-based groundwater screening concentrations that result in acceptable indoor air concentrations were calculated for the various contaminants of concern at the Base. The calculations utilized a simple box model (ASTM 1995, Standard Guide for Risk-Based Corrective Action Applied at Petroleum Release Sites, E1739-95) to conservatively represent the transfer of volatile constituents to buildings. The groundwater screening concentrations are presented in Table 4-6. Detected groundwater concentrations less than or

TABLE 4-6

Indoor Air Inhalation Risk Calculation

Notes:

1. 1E-02 = 0.01
2. SSSLair = Site Specific Screening Level for air, the minimum of the acceptable air concentration based on carcinogenic effects and the acceptable air concentration based on noncarcinogenic effects.
3. The toxicity information is based on the most current information available from IRIS (USEPA, December 1, 2000) and on other information compiled by USEPA Region 09 (2000).
4. Calculation of acceptable air concentrations followed methods developed by USEPA (1996) and USEPA Region 09 (2000).

Model Parameters

Inhalation Rate (adult)		1.9	m^3/hour	(ODEQ, 2000)
Exposure Time		8	hours/day	(ODEQ, 2000; based on an 8-hour work day)
Exposure Frequency		250	days/year	(ODEQ, 2000; USEPA, 1991, USEPA Region 09, 2000)
Exposure Duration (adult)		20	years	(site-specific, based on a 20 year enlistment in the Armed Services)
Body Weight (adult)		70	kilograms	(ODEQ, 2000; USEPA, 1991, USEPA Region 09, 2000)
Averaging Time (carcinogens)		25550	days	(ODEQ, 2000; USEPA, 1991, USEPA Region 09, 2000)
Averaging Time (noncarcinogens)		7300	days	(ODEQ, 2000; USEPA, 1991, USEPA Region 09, 2000)
volumetic air content (capillary fringe)	øacap =	3.80E-02	(dimensionless)	(ASTM, 1996)
volumetic air content (foundation cracks)	øacrack =	2.60E-01	(dimensionless)	(ASTM, 1996)
volumetic air content (vadose zone)	øas =	2.60E-01	(dimensionless)	(ASTM, 1996)
total soil porosity	øtotal =	3.80E-01	(dimensionless)	(ASTM, 1996)
volumetric water content (capillary fringe)	øwcap =	3.42E-01	(dimensionless)	(ASTM, 1996)
volumetic water content (foundation cracks)	øwcrack =	1.20E-01	(dimensionless)	(ASTM, 1996)
volumetic water content (vadose zone)	øws =	1.20E-01	(dimensionless)	(ASTM, 1996)
thickness of capillary fringe	hcap =	5.00E+00	cm	(ASTM, 1996)
thickness of vadose zone	hvadose =	1.47E+02	cm	(Site-specific assumption, based on a depth of 5 feet to groundwater)
air exchange rate	ER =	3.00E-04	sec^-1	(Site-specific assumption, based on 1 unit volume air exchange per hour)
enclosed space volume/infiltration area ratio	Lb =	6.10E+02	cm	(Site-specific assumption, based on buildings that are approximately 20 feet tall)
depth to ground water (= hcap + hvadose)	Lgw =	1.52E+02	cm	(based on a depth of 5 feet to groundwater)
foundation thickness	Lcrack =	1.50E+01	cm	(ASTM, 1996)
areal fraction of foundation cracks	n =	1.00E-02	(dimensionless)	(ASTM, 1996)
Henry's Law Constant (dimensionless form)	H' =	chemical specific		(USEPA Region 09, 2000)
Diffusion coefficient (air)	Da =	chemical specific		(USEPA Region 09, 2000)
Diffusion coefficient (water)	Dw =	chemical specific		(USEPA Region 09, 2000)

Deff(cap) = [Da x (øacap^3.33)/(øtotal^2)] + [Dw x (1/H') x (øwcap^3.33)/(øtotal^2)] (ASTM, 1996)

Deff(soil) = (Da x (øas^3.33)/(øtotal^2)) + [Dw x (1/H') x (øws^3.33)/(øtotal^2)] (ASTM, 1996)

Deff(ws) = (hcap + hv)/[(hcap/Deff(cap)) + (hv/Deff(soil))] (ASTM, 1996)

Deff(crack) = (Da x (øacrack^3.33)/(øtotal^2)) + [Dw x (1/H') x (øwcrack^3.33)/(øtotal^2)] (ASTM, 1996)

VFwesp = {1000 l/m^3 x H' x [(Deff(ws)/Lgw)/(ER x Lb)]}/{1 + [(Deff(ws)/Lgw)/(ER x Lb)] + [(Deff(ws)/Lgw)/(n x Deff(crack)/Lcrack)]} (ASTM, 1996)

SSSL (water) = SSSL(air)/VFwesp (ASTM, 1996)

equal to these screening levels will not pose an unacceptable risk (as defined by ODEQ regulations) to workers who may be present in these buildings.

VOCs in groundwater at some locations at the Base currently exceed the screening concentrations of some of the compounds listed in Table 4-6. However, the only occupied buildings near impacted groundwater are Buildings 255 and 260 in the vicinity of IRP Site 11. Chlorinated VOCs, primarily VC and cis-1,2-DCE, have been detected in groundwater monitoring wells near these buildings, but recent monitoring has shown that these compounds are at concentrations much less than those calculated in Table 4-6. Because of this, potential indoor air exposures for site personnel currently working in these buildings are acceptable under ODEQ regulations. Furthermore, groundwater concentrations are expected to decrease to concentrations below the indoor air screening levels as a result of interim remedial actions for groundwater. Thus, in the event that a new building is constructed on the Base, indoor air exposures are not expected to pose an unacceptable risk under future conditions. For these reasons, the indoor air inhalation exposure pathway was not retained for further evaluation in this FS.

The exposure pathways retained for the FS include ingestion of CRSA groundwater pumped from municipal wells that would be installed in the Portland well field WEA and ingestion of CRSA groundwater pumped at the Base by Base workers. Neither pathway currently exists, and the pathway involving extraction of CRSA groundwater at the Base is not likely. However, because the CRSA has the capacity to support these scenarios, they must be considered.

Clean-Up Levels and Applicable Criteria. Future RA taken at the Portland ANGB must comply with Federal, State, and local laws and regulations, as discussed in the ARARs section above. In accordance with USEPA guidance, chemical-, action-, and location-specific ARARs have been identified for the COCs at the Portland ANGB.

The RAOs for the Portland ANGB correspond with the exposure pathways and Federal and State requirements. The RAOs are as follows:

- Prevent off-site migration of groundwater containing VOCs above 10^{-6} risk concentrations for individual carcinogens;

- Treat groundwater hot spots of contamination (as defined by ODEQ guidance) to concentrations below significant adverse effect levels which correspond with the Federal MCLs;

- Treat the small area of VOC and TPH impacted soil remaining from the 1999 soil removal action; and

- Prevent on-site exposure to groundwater containing VOCs above 10^{-6} risk concentrations for individual carcinogens.

4.3 General Response Actions

General response actions are broadly defined as measures designed to prevent or minimize the adverse environmental impacts of chemicals, and satisfy the RAOs. Appropriate general response actions for IRP Sites 2, 9, and 11 have been identified based on data collected during the RI and pilot tests performed at the Base. The general response actions developed for remediation of groundwater include:

- No action;

- Institutional controls;

- Engineering controls;

- Groundwater collection, treatment, and discharge; and

- In situ groundwater treatment.

4.3.1 No Action

No Action is a general response action required for consideration in the FS by the National Contingency Plan as a baseline condition. The No Action option is retained for further evaluation. There are no costs associated with this option.

4.3.2 Institutional Controls

Institutional controls are designed to limit exposure to hazardous materials through the use of legal or administrative measures or actions. The technologies and process options developed under the institutional control general response action are briefly described in Table 4-7. Three

TABLE 4-7

Remedial Technology Screening - IRP Sites 2, 9, & 11
142nd FW, Portland ANGB, Portland, Oregon

Risk Drivers	Remedial Action Objectives	General Response Action	Remedial Technologies	Process Options	Description	Effectiveness[1]	Implementability[1]	Cost Effectiveness[1]	Retain?	Reason
Trichloroethene, cis-1,2-Dichloroethene, trans-1,2-Dichloroethene, and Vinyl Chloride in Groundwater	Prevent the off-base migration of groundwater containing VOCs above concentrations corresponding to a Hazard Index greater than 1 or a lifetime excess cancer risk greater than 1x10-6 for individual carcinogens.	**No Action**	No Action	No Action	No institutional controls or treatment.	1	3	3	Yes	Retaining No Action is required for comparison.
		In Situ Treatment - Source area will be treated to reduce VOC concentrations sufficiently to prevent off-base migration of groundwater with unacceptable risk. Preliminary target cleanup levels are MCLs, which will also be protective of human health on site based on an industrial land use scenario	Chemical treatment	Permanganate oxidation	Injection of potassium permanganate into saturated zone. Contaminants are destroyed through oxidation.	3	3	2	Yes	Pilot-scale treatability testing at Base indicates potential for full-scale effectiveness.
				Persulfate oxidation	Injection of sodium persulfate into saturated zone. Contaminants are destroyed through oxidation.	3	3	2	Yes	Persulfate's anticipated effectiveness at treating benzene serves as a substitute or amendment for permanganate when treating benzene is the objective.
				Fenton's Reagent oxidation	Injection of a mixture of hydrogen peroxide and an iron-based catalist. The breakdown of hydrogen peroxide produces hydroxyl radical, which destroys contaminants through oxidation.	3	2	2	No	Safety concerns associated with the use of concentrated hydrogen peroxide are too great. This technology does not provide a significant residual treatment capacity, relative to potassium permanganate.
				Ozone Sparging	Sparging of ozonated air into saturated zone. Contaminants are destroyed through oxidation.	3	2	2	Yes	Pilot-scale treatability testing at Base indicates potential for full-scale effectiveness.
				Zero Valent Iron Oxidation	Construction of a reactive barrier wall using zero valent iron. VOCs in groundwater flowing through wall are oxidized.	1	2	1	No	The slowness and variability of groundwater flow at the Base are not compatible with this type of technology.
			Biological Treatment	Enhanced aerobic bioremediation	Injection of oxygen releasing substance into saturated zone stimulates activity of aerobic microbes. Applicable to contaminants capable of aerobic degradation.	3	3	2	Yes	Treatability testing at Base indicates potential for full-scale effectiveness.
				Enhanced anaerobic bioremediation	Injection of hydrogen releasing substance into saturated zone stimulates activity of anaerobic microbes. Applicable to contaminants capable of anaerobic degradation.	3	3	2	Yes	Testing at sites with similar conditions indicate potential effectiveness at treating TCE in groundwater.
			Physical Treatment	In-well Aeration	In-well aerators perform air stripping of groundwater within the well. Groundwater is not removed from the well, but is circulated through the aquifer.	3	2	2	Yes	Pilot-scale treatability testing at Base indicates potential for full-scale effectiveness.
				Air Sparging	Sparging of air into saturated zone volatilizes contaminants. Contaminants are transferred to vapor phase. This technology is usually combined with soil vapor extraction and off-gas treatment to control release of volatilized contaminants.	2	2	2	No	Requirement for soil vapor extraction wells and the expected duration of this technology results in reduced cost-effectiveness.
			Monitored Natural Attenuation	Intrinsic Bioremediation	Involves monitoring parameters used to quantify natural biodegradation of contaminants.	2	3	3	Yes	Natural attenuation has been shown to be slow, but active at the Base. Use of natural attenuation should be used only at lower concentration areas of contaminant plumes, or as a polishing method following active treatment.
		Groundwater Collection / Treatment / Discharge	Groundwater extraction	Groundwater extraction wells	Use of groundwater extraction wells to pump groundwater out of the aquifer for treatment and disposal.	2	2	1	No	Pump and treat technologies are not expected to be cost-effective relative to in situ treatment technologies.
			Physical Treatment	Air stripping	Countercurrent flow of air and water transfers VOCs from aqueous phase to vapor phase.	2	2	2	No	Pump and treat technologies are not expected to be cost-effective relative to in situ treatment technologies.

TABLE 4-7

Remedial Technology Screening - IRP Sites 2, 9, & 11
142nd FW, Portland ANGB, Portland, Oregon

Risk Drivers	Remedial Action Objectives	General Response Action	Remedial Technologies	Process Options	Description	Effectiveness[1]	Implementability[1]	Cost Effectiveness[1]	Retain?	Reason
			Off-site discharge	Discharge to POTW	Discharge of extracted and treated groundwater to the sanitary sewer for conveyance to the local POTW.	2	2	3	No	Pump and treat technologies are not expected to be cost-effective relative to in situ treatment technologies.
Trichloroethene, cis-1,2-Dichloroethene, trans-1,2-Dichloroethene, and Vinyl Chloride in Groundwater (continued...)	Prevent the off-base migration of groundwater containing VOCs above concentrations corresponding to a Hazard Index greater than 1 or a lifetime excess cancer risk greater than 1x10-6 for individual carcinogens. (continued…)	**Institutional Controls**	Monitoring	Groundwater monitoring	Regular monitoring of groundwater to evaluate effectiveness in meeting remedial action objectives.	1	3	3	Yes	Groundwater monitoring will be required to evaluate an alternative's effectiveness at meeting remedial action objectives.
			Land / Water use restrictions	Deed Restrictions	Deed restrictions create legal restrictions on specific activities or uses of land or water by current and future land owners.	3	3	3	Yes	Deed restrictions are necessary to prevent unrestricted use of the Base.
				Zoning restrictions	Zoning restrictions prevent the alteration of the zoning classification of the Base.	3	3	3	Yes	Zoning restrictions are necessary to prevent alteration of the zoning classification of the Base.
				Access restrictions	Access restrictions prevent use of a facility by unauthorized personnel and for unauthorized purposes.	3	3	3	Yes	Access restrictions are necessary at the Base to prevent unrestricted access to potentially contaminated sites.
			Construction Controls	Health and safety training, equipment, and monitoring	Construction activities performed in areas containing potentially elevated levels of contaminants must be accompanied by appropriate health and safety monitoring. Construction workers must be appropriately trained and properly equipped.	3	3	3	Yes	Construction activities, excavation below the water table in particular, must be performed in a manner protective of worker health.
		Engineering Controls	Alternative water supplies	Public water system	This option specifies that the Base must tap into the public water system for future water supplies, rather than drilling supply wells on the Base.	3	3	3	Yes	Future water supplies for drinking or process use must not be obtained from Base groundwater.

NOTES:

VOC - Volatile organic compound

MCL - Maximum Contaminant Level

POTW - Publicly Owned Treatment Works

TCE - Trichloroethylene

1 - Effectiveness, implementability and cost effectiveness evaluated on a relative 1 to 3 scale, where 1 is low and 3 is high.

institutional control technologies were screened: monitoring, land- or water-use restrictions, and construction controls. Process options for monitoring consist solely of groundwater monitoring. Process options for land and water use restrictions include deed and zoning restrictions. Process options for construction controls consist of implementing health and safety procedures including training, equipment, and monitoring.

4.3.3 Engineering Controls

Engineering controls are designed to limit exposure to hazardous materials through the use of physical measures. The technologies and process options developed under the engineering control general response action are briefly described in Table 4-7. The engineering control technology that was screened involved alternative water supplies. Process options for alternative water supplies are limited to obtaining new water supplies from the public water system.

4.3.4 Groundwater Collection, Treatment, and Discharge

This general response action involves collection, treatment, and discharge of site groundwater. This action would be performed to reduce concentrations of contaminants in site groundwater to levels required to meet RAOs. Technologies screened under this general response included groundwater extraction, physical treatment, and off-site discharge. The process options for these technologies are groundwater extraction wells, air stripping, and discharge to a POTW. These process options are described briefly in Table 4-7.

4.3.5 In Situ Groundwater Treatment

This general response action involves in situ treatment of site groundwater to meet RAOs. Technologies screened for in situ treatment include chemical treatment, biological treatment, physical treatment, and action monitored natural attenuation (MNA). The process options screened for the chemical treatment technology included zero-valent iron oxidation, Fenton's reagent oxidation, permanganate oxidation, persulfate oxidation, and ozone sparging. The biological treatment process options include enhanced aerobic and anaerobic bioremediation. The physical treatment process options include in-well aeration and air sparging. The sole process option for MNA involves monitoring the intrinsic

bioremediation element of natural attenuation. Table 4-7 provides a brief description and evaluation of these process options.

4.4 Identification and Screening of Remedial Technologies

Following the development of general response actions (Section 4.3), potentially suitable remedial technologies have been identified and screened (i.e., retained or discarded from further consideration). In this process, a set of potentially applicable remedial technologies and process options are identified and generally evaluated with respect to implementability and effectiveness at the site considering the RAOs, the COCs, and the physical/chemical site characteristics.

Based on readily available information for technologies applicable to the types of contaminants and site characteristics at the Portland ANGB, assumptions can be made regarding the initial set of technologies and process options. While it is possible to list dozens of technologies and systematically eliminate a large majority of those due to an obvious lack of applicability, this FS is based on a reasonable subset of technologies specifically applicable to the RAOs, COCs, and site characteristics for the Portland ANGB.

This subset of treatment technologies described below represents: 1) a list of technologies that have been tested at the Base; 2) are proven technologies for the particular application; or 3) are innovative technologies expected to successfully meet remediation objectives. Technologies that are not expected to be implementable or effective at the base were not evaluated in this FS. Examples include technologies such as thermal processes, capping, hydraulic barriers, and numerous ex-situ treatment technologies. It is acknowledged that these technologies have been used as remediation options at sites impacted with similar contaminants. However, due to site restrictions, hydrogeologic constraints, or other factors at the Portland ANGB, these technologies are not expected to be applicable to groundwater treatment at the Portland ANGB.

The remedial technologies and process options identified for each general response action category are shown in Table 4-7. For each technology, at least one process option was selected. These process options are briefly described in Table 4-7. A relative screening is also presented in this table, which served as the basis for a recommendation to either retain or exclude a particular process option from further consideration. Comments also

provide a basis for the screening decision. The technologies identified for remediation of groundwater include:

- No action;
- Monitoring;
- Land / water use restrictions;
- Construction controls;
- Alternative water supplies;
- Groundwater extraction and treatment;
- In situ chemical treatment;
- In situ biological treatment;
- In situ physical treatment; and
- MNA.

These remedial technologies are described below under the appropriate general response actions.

4.4.1 No Action

Under the No Action general response action, No Action was the only technology / process option proposed. Under the No Action option, site modifications or groundwater monitoring would not be implemented to prevent or eliminate human health and environmental risks associated with VOCs in groundwater.

This alternative does not reduce or control potential future risk posed by groundwater contaminants at IRP Sites 2, 9, or 11. Because the alternative excludes remedial, institutional, and monitoring activities, it is considered easily implemented. There is no cost associated with this alternative.

Consideration of No Action as a technology is required in the FS process for comparison purposes; therefore this option is retained for further evaluation.

4.4.2 Institutional Controls

The Institutional Controls general response action includes consideration of three remedial technologies or processes: monitoring, land/water use restrictions, and construction controls. These technologies and the relative process options are described below.

4.4.2.1 Monitoring

Monitoring is an institutional control used to evaluate the presence of COCs at specific locations. This technology is used to evaluate the migration of VOCs at the Base to ensure compliance with the RAOs. The single monitoring process option used for this FS is groundwater monitoring. Specific existing and proposed monitoring wells screened in the various water-bearing zones underlying the Base will be monitored at regular intervals.

4.4.2.2 Land-/Water-Use Restrictions

The use of land- and water-use restrictions as a remedial technology/process involves placing restrictions on the current and future uses of the land and groundwater within the Base boundary. Several process options are available for this purpose, including deed restrictions, zoning restrictions, and access restrictions. Implementing these restrictions protects Base workers and future residents of the Base property, should a property transfer occur.

Deed restrictions create legal restrictions on specific activities or uses of land or water by current and future landowners. These restrictions are intended to prevent unauthorized development of the land and water.

Zoning restrictions are similar to deed restrictions, but prevent the future alteration of land use classification. This would prevent the Base from later being designated mixed use or residential use.

Access restrictions prevent unauthorized access or use of the Base. This would prevent unauthorized access to areas containing unacceptable levels of contaminants.

4.4.2.3 Construction Controls

The use of construction controls involves control and monitoring of construction crews at the Base to prevent unhealthy exposure to

contaminants by construction personnel. During excavation activities, construction workers may be exposed to shallow groundwater containing VOCs. The one process option for this technology involves implementing a site-specific health and safety program consisting of training construction workers, providing appropriate equipment, and monitoring work areas to prevent contaminant exposure during construction.

4.4.3 Engineering Controls

The engineering controls general response action includes consideration of one technology: alternative water supplies. This technology is described below.

4.4.3.1 Alternative Water Supplies

As an engineering control, alternative water supplies provide an option for obtaining additional water at the Base. To prevent the need to drill production wells on the Base, alternative water supplies must be available to supply additional water needs. Process options for alternative water supplies are limited to obtaining new water supplies from the public water system.

4.4.4 Groundwater Extraction and Treatment

Groundwater extraction and treatment is a general response action category that involves a number of traditional technologies and process options for groundwater remediation through contaminant migration control and contaminant mass removal methods. Based on the site characteristics and the nature and extent of contamination, only one technology is presented here for discussion. While several process options are available to extract groundwater from the subsurface (trenches, horizontal piping, vacuum systems, etc.) the process option identified and screened for the Portland IRP sites involves the use of groundwater pumping wells placed at specified intervals in the Shallow and Deep Zones. Dissolved contaminants in groundwater would be captured via pumping processes, extracted to the surface, physically or chemically treated, and disposed through one of several potential process options (e.g. disposal to an off-site POTW, re-infiltration, etc.).

While the dissolved contaminants present at IRP Sites 2, 9, and 11 are susceptible to capture and removal by pumping processes, the success of groundwater extraction technologies is highly dependant on the ability to

efficiently pump contaminated water from the water bearing zone. Often this success is measured in terms of the efficiency, or the mass of contaminant removed per unit cost to operate the system.

Lithologic data from the RI indicate that the thickness of the Shallow and Deep Zones vary significantly over short distances, and that significant silty intervals are present in both zones. Also, the silty intervals bracketing the zones are saturated. These conditions are problematic for successful remediation by groundwater extraction, as VOCs have a moderately strong affinity for sorption to fine-grained soil particles and because preferential flow pathways can be expected to develop in coarser-grained intervals within the Shallow and Deep Zones.

The low storativity values estimated from groundwater pumping test data also indicate that even relatively low groundwater pumping rates (i.e., 5 gallons per minute) would significantly lower the groundwater level in the overlying silt and, likely, the upper Shallow Zone. Much of the residual VOCs sorbed to soils would be stranded above the zone in which flushing would be achieved by groundwater flow toward the extraction wells. For these reasons, it is unlikely that groundwater extraction would cost-effectively remediate VOCs in groundwater.

This technology was not retained for evaluation in this FS because Shallow Zone hydrogeologic characteristics are not favorable for effective contaminant reduction through groundwater extraction. Since groundwater extraction technology has not been retained as a feasible remedial option, no further discussion of physical treatment or off-site discharge with regard to the groundwater extraction and treatment general response action is necessary.

4.4.5 In Situ Groundwater Treatment

Several remedial technologies were screened for the in situ groundwater treatment general response action. These technologies included chemical, biological, and physical treatment, as well as MNA. Descriptions are provided below.

4.4.5.1 Chemical Treatment

In situ chemical treatment of groundwater contaminants involves the chemical alteration or destruction of the contaminants through processes carried out in the saturated zone, without the need to extract groundwater. Generally, this technology involves the injection of a

reactive chemical or mixture of chemicals that reacts with the particular COCs.

The most common mechanism for the in situ chemical treatment of VOCs is oxidation. In situ oxidation is a relatively new technology that involves the placement of an oxidant into the subsurface to react with the COCs. In situ oxidation is applicable for various organic contaminants, including fuel-related hydrocarbons and VOCs, chlorinated VOCs, and PAHs. Because of the wide availability and observed success of oxidation technologies, other in situ chemical treatment mechanisms were not evaluated in this FS.

The potential benefits from in situ oxidation include in situ contaminant destruction, relatively low cost, reliability, simplicity, and rapid treatment. However, site-specific constraints must be considered. Efficient oxidation is dependent on the contact between oxidant and contaminant. Subsurface heterogeneities, preferential flow paths, and poor mixing in the subsurface may result in inefficient treatment. In addition, high levels of other oxidizable substances in the treated zone, such as other organic material and reduced-state metals, can significantly reduce the treatment efficiency and effectiveness.

The primary delivery mechanism for in situ chemical oxidation involves the placement, through fluid injection, gaseous sparging, or bulk soil replacement, of the oxidizing material in the zone of contaminated groundwater being treated. ODEQ is likely to consider all of these mechanisms to be regulated under their UIC program, thus requiring that injection locations be registered and the requirements described in Section 4.1.3.6 be met. The primary concern with in situ oxidation is the long-term degradation of water quality beyond the zone of treatment. All of the technologies described below have the potential to cause unacceptable water quality degradation under certain conditions.

Some potential water quality degradation mechanisms are common to all oxidation processes. For example, the altered oxidation state of the subsurface resulting from in situ oxidation can cause the migration of metals such as chromium that are more soluble and potentially more toxic in their oxidized state. However, dissolved chromium has not been regularly detected in groundwater during the RI at areas being considered for in situ oxidation and chromium concentrations detected in soil have been well below regulatory limits. Due to an induced oxidative state and slightly increased pH, some chromium may oxidize to the hexavalent form and become mobile. However, this transformation is highly dependent on the pH and redox potential of the groundwater (Zumdahl

1989). As groundwater flows away from the area immediately surrounding the treatment location, or as the oxidant is utilized, pH and redox values will decrease until they reach initial conditions. As pH and redox values equilibrate, the equilibrium concentration of hexavalent chromium will decrease significantly.

Other hazards or potential mechanisms for degradation of water quality specific to a particular oxidation technology will be addressed below.

The five chemical treatment process options that have been retained for evaluation in this FS are zero-valent iron oxidation, Fenton's Reagent oxidation, potassium permanganate oxidation, sodium persulfate oxidation, and ozone sparging, all of which rely on the oxidation of contaminants.

Zero-Valent Iron Oxidation

Metallic iron has been used successfully to oxidize subsurface contaminants, including VOCs. This technology is generally applied as a funnel and gate or standard reactive-barrier wall and relies on the horizontal flow of groundwater past a wall of iron in the form of granules or filings. The wall of iron is constructed by excavating the soil from the top of the water-bearing zone down to the confining layer and replacing the soil with iron and other wall components.

The advantage of an iron reactive barrier wall is that the treatment is performed passively, as groundwater flows past the wall. The only maintenance required would be replacement of the iron as its oxidation capacity reduces. The main disadvantage of this technology is that it relies on the horizontal flow of groundwater past the reactive wall.

The introduction of solid zero-valent iron has the potential to cause a degradation of water quality. As described previously, the oxidative state induced by the iron has the potential to cause dissolution of heavy metals such as hexavalent chromium. The potential for this to occur is based on the reactive life span of the iron. If the iron is allowed to remain in place and the oxidative effects are long lived, the original conditions of the water-bearing zone being treated may not readily equilibrate, allowing oxidized metals to migrate further than some other technologies. Also, small quantities of other metals such as chromium, arsenic, and cadmium may be present in the granular iron used for this technology. The contaminants introduced by this technology may impact water quality if present at high levels.

Because horizontal groundwater flow at the Portland ANGB is relatively slow and directionally variable, and the primary exposure scenario relies on the downward flow of groundwater and contaminants, this technology would not be expected to meet the RAOs. Therefore, zero-valent iron oxidation is not retained for further evaluation in this FS.

Fenton's Reagent Oxidation

The chemistry of Fenton's reagent involves the production of hydroxyl radicals through the catalysis of hydrogen peroxide. Ferrous iron (Fe^{2+}), either in native soil or delivered in the form of iron salts such as ferrous sulfate, catalyses the breakdown of hydrogen peroxide and the production of the hydroxyl radical.

The use of Fenton's reagent chemistry as an in situ remediation technology has been developed in several proprietary, commercially available forms. The hydrogen peroxide is mixed with iron salts and other proprietary components and delivered to the groundwater treatment zone in the same manner as other in situ fluid delivery technologies. This technology is applicable for a wide range of organic contaminants, including free phase contamination. The reactivity of the hydroxyl radical is very high and rapid.

There is a limit to the effectiveness of Fenton's Reagent by virtue of it's relative environmental instability . Hydroxyl radicals are relatively short lived. The hydroxyl radical will react with free radical scavengers / sinks and eventually be destroyed. Free radical sinks include metals, natural organics, or hydrogen peroxide itself. When the hydroxyl radicals react with hydrogen peroxide, heat and gas are produced. Because of the threat of rapid decomposition, 5-10 percent hydrogen peroxide solution is considered as a relatively safe range for the application of hydroxyl radicals. Above this concentration the decomposition of peroxide is sufficiently exothermic to produce steam, which if not captured in an engineered fashion can create safety hazard, as encountered in a few field-applications. The floodplain silts confining the Shallow Zone and Deep Zone water bearing units at the Base would prevent the gradual release of any steam or VOC vapors produced from this reaction. This could produce a buildup of high pressure, resulting in a dangerous sudden release through a preferential pathway, such as a monitoring well or utility vault. This potential scenario would be unacceptable at the Base, particularly at IRP Site 11 where aircraft and aircraft fuel are stored.

Because of the instability and potential heat and steam production due to the reaction of hydrogen peroxide, this technology was not retained for further evaluation in this FS.

Potassium Permanganate Oxidation

One of the most common oxidants available for use in the chemical treatment of organic contaminant is potassium permanganate. Potassium permanganate is delivered into the water-bearing zone as a water-based solution of approximately 1 to 5 percent potassium permanganate, by weight. Upon dissolution, permanganate ion causes the solution to turn purple, which provides an indicator mechanism. When the permanganate is reduced upon reaction with organic matter, it forms manganese dioxide, which is an insoluble brown precipitate under most conditions. In some cases, the manganese dioxide can cause a slight reduction of hydraulic conductivity in the treatment area (Environmental Security Technology Certification Program 1999). Permanganate is very effective at oxidizing most VOCs, and is capable of oxidizing petroleum hydrocarbons and related compounds. Permanganate has not been proven to be as effective at treating benzene as some other compounds.

Potassium permanganate has been proven to provide effective treatment of the chlorinated VOCs impacting groundwater at IRP Sites 2 and 11. Potassium permanganate is the least expensive oxidant available. A remediation system consisting of injecting potassium permanganate using direct-push injection points or permanent injection wells can be significantly less expensive than constructing a continuously operating remediation system. Permanganate injection can also be performed using horizontal wells. This will allow use of this technology when disturbing the ground surface above the treatment area is not feasible.

The COCs at IRP Site 9 require different considerations when choosing an appropriate oxidant. In particular, benzene has been shown to react slowly when treated with potassium permanganate.

A pilot test using injection of potassium permanganate was conducted at IRP Site 2. The purpose of the test was to evaluate the effectiveness of potassium permanganate at treating chlorinated VOCs in Shallow Zone groundwater and to determine a radius of influence for the injection. Significant reduction of chlorinated VOC concentrations in groundwater was observed. Over a 3-month monitoring period, VC was reduced by between 80 percent and greater than 90 percent at downgradient monitoring wells. Significant removal of cis-1,2-DCE and trans-1,2-DCE was also observed (up to 90 percent). Significant reduction of VC (greater

than 80 percent) and trans-1,2-DCE (approximately 75 percent) were observed at the furthest monitoring well, 12-feet downgradient of the injection location. Further details regarding the results of this pilot test are provided in the *Interim Remedial Action Construction Phase I Interim Report* (ERM 2001c).

Potassium permanganate reacts rapidly with the double bonds in chlorinated ethenes. Permanganate oxidizes the chlorinated ethenes to carbon dioxide and chloride ion. The end products of the reaction of potassium permanganate with CVOCs are carbon dioxide, water, hydroxide ion, potassium ion, manganese dioxide, and chloride ion. For example, the reaction of potassium permanganate with VC is represented in the following balanced stoichiometric equation:

$$10KMnO_4 + 3C_2H_3Cl \text{ ---> } 6CO_2 + 10MnO_2 + 10K^+ + 3Cl^- + 7OH^- + H_2O$$

The end products are not expected to cause a detrimental impact to groundwater quality. Unreacted permanganate can discolor groundwater (purple color). However, unreacted permanganate is not expected to reach a receptor, because the natural oxidant demand of native materials in the soil and groundwater will cause the permanganate to react with these materials before the permanganate can migrate a significant distance. This behavior was confirmed during the Phase I IRAC (ERM 2001c), where purple colored groundwater was not observed at a significant distance downgradient.

When the permanganate is reduced upon reaction with organic matter, it forms manganese dioxide, which is an insoluble brown precipitate under most conditions. However, precipitated manganese dioxide is not expected to inhibit groundwater flow at the low concentration of potassium permanganate that will be injected.

The raw material used for this technology is technical grade solid potassium permanganate. This is the same material used in drinking water and wastewater treatment, and its composition is regulated by the American Water Works Association. It is possible that the material used could contain trace amounts of impurities from the manufacturing process. These impurities could include toxic heavy metals such as chromium and mercury at very low concentrations. One manufacturer of potassium permanganate lists typical values of the three regulated impurities as less than 5 mg/kg cadmium, less than 20 mg/kg chromium, and less than 0.5 mg/kg mercury. At the concentration of potassium permanganate to be injected into the groundwater at IRP Site 11, the resulting concentrations of these three metals will be less than their

respective MCLs. As the injectate disperses and mixes with groundwater immediately surrounding the injection location, the resulting concentrations will decrease further. For verification, a sample of the raw material will be analyzed for impurities.

The long-term effects of potassium permanganate injection are expected to be favorable for subsequent natural attenuation of low concentrations of the remaining chlorinated VOCs in groundwater. Although the oxidative environment caused by the injected potassium permanganate may temporarily inhibit intrinsic biodegradation in the treatment area, intrinsic biological activity is expected to resume at pre-treatment levels soon after this oxidative environment attenuates.

The United States Department of Energy (DOE) evaluated the use of potassium permanganate in an Innovative Technology Summary Report titled *In Situ Chemical Oxidation using Potassium Permanganate* (DOE 1999). The DOE made several conclusions regarding the use of potassium permanganate and associated community and regulatory issues. Among the conclusions of the DOE evaluation were the following:

- The materials injected ($KMnO_4$) pose no hazard to the community or environment due to their low concentration after dispersal into the soil or groundwater;

- The community is not exposed to harmful by-products and there is no significant environmental impact as the overall reaction results in generation of carbon dioxide, MnO_2 solids, cations (e.g., potassium), and halides (when chlorinated solvents are present);

- In situ chemical oxidation using $KMnO_4$ does not produce VOCs (due to cleavage of the organic compound); and

- No unusual or significant safety concerns are associated with transport of equipment or other materials associated with this technology.

Persulfate Oxidation

Persulfates are strong but slow reacting oxidants. They exist as salts and are commonly available as the sodium, potassium or ammonium forms. Persulfates require activation in order to react, due to their high activation energy. They are typically thermally activated in industrial use.

Activation through the use of metal catalysis such as iron catalysis is also possible. The application of persulfates in groundwater remediation has not been tested extensively, but is expected to be effective based on

chemical reaction data (Brown 1999). The application of persulfate is similar to that for potassium permanganate. A water-based solution is injected through injection wells or direct-push injection points.

Persulfate is expected to be effective primarily for benzene and is not expected to effectively treat chlorinated VOCs. This option would be useful at IRP Site 9, for treating benzene.

Water quality issues for persulfates are similar to that of permanganate since the reaction mechanism is essentially the same. Persulfate is similarly a strong oxidant and will induce oxidative conditions in the water-bearing zone. However, as with the application of potassium permanganate, the persulfate is injected in low concentrations and the effects of this injection will not be seen at a great distance from the treatment zone. The use of persulfate oxidation is only proposed at IRP Site 9, where chlorinated hydrocarbons are not present. Because of this, production of more toxic VOCs is not a concern.

The composition of sodium persulfate and appropriate catalysts must be analyzed to prevent introduction of contaminants that may degrade water quality.

Ozone Sparging

The chemical process of in situ oxidation using ozonation is very similar to permanganate oxidation. Ozone is a strong oxidizer that readily breaks down organic compounds. Chemical oxidation by ozone is applicable for various organic contaminants including fuel-related hydrocarbons and VOCs, chlorinated VOCs, and PAHs.

Ozone sparging significantly differs from the other oxidation technologies, in that the implementation of ozone sparging is significantly more complex than that required for liquid injection. Ozone is delivered to the contaminated zone in the gas phase. Ozone is sparged using a typical air-sparging system, with the addition of between 1 and 5 percent ozone gas, by weight, to the air to be sparged. The gas mixture flows upward, oxidizing organic material in the process. Ozone can also be delivered through horizontal wells. Horizontal sparge wells installed near the bottom of the treatment zone can provide effective distribution of sparged gasses.

Ozone is the strongest oxidant available for remediation and is very effective at oxidizing most organic contaminants. However, because ozone is so reactive in nature, it does not provide the stable, residual

treatment capacity of some other oxidants, including permanganate. Also, ozone sparging is very susceptible to preferential flow, which can lead to pockets of untreated contaminants in heterogeneous soil.

Ozone sparging has been proven to provide efficient treatment of contaminants under the correct conditions. The COCs at IRP Sites 2, 9, and 11, chlorinated VOCs and benzene can all be treated effectively by ozone sparging.

The only water quality issues related to this technology is that related to the induced oxidative state of the groundwater as previously described. However, because ozone is so short-lived, the oxidative effects do not remain as long as other technologies. This is why an ozone system must be continuously operated. Oxidative effects of the ozone will not travel very far outside of the treatment zone. Native material in soil will quickly utilize any available ozone. There are no other byproducts of the oxidation reactions that would be expected to cause degradation of water quality at the Portland ANGB. However, there are safety concerns associated with ozone sparging. Ozone leaking from a system prior to being injected into the subsurface can pose a health and explosion hazard if in significant concentrations. Also, since this technology relies on the continuous injection of a gas into the subsurface, the use of pressure relief points in the subsurface must be considered, particularly in a confined water-bearing zone.

A pilot test using ozonation was conducted at IRP Site 2. The purpose of the test was to evaluate the effectiveness of ozone at treating chlorinated VOCs in Shallow Zone groundwater and to determine a radius of influence for the sparging system. Reduction of chlorinated VOC concentrations in groundwater was observed in nearby wells. Following 24-hours of ozone sparging, concentrations of cis-1,2-DCE and trans-1,2-DCE were reduced by approximately 75 percent. Contaminant removal was not observed in the furthest downgradient monitoring well at a distance of 12-feet. However, a significant change in wellhead VOC concentration was observed in this well during air sparging and ozone sparging, indicating some influence at this distance. Since contaminant reduction was not observed at this well, it must be concluded that the true radius of influence of the system is less than 12-feet.

The radius of influence for this system was estimated to be 8 to approximately 9-feet (ERM 2001c).

4.4.5.2 Biological Treatment

In situ biological treatment involves the injection of a material that stimulates the natural biological activity of the contaminated zone. The natural biological activity of a contaminated zone can become depressed after an extended period of contaminant degradation. Some sites are capable of extensive contaminant removal if depleted growth factors are replenished. Biological activity in a contaminated zone is frequently limited by the availability of a single growth factor, such as an electron acceptor or donor. Supplying this growth factor can often stimulate bacterial growth and biodegradation rates, and is generally used to treat saturated zone contamination.

The COCs at IRP Sites 2, 9, and 11 are expected to be treatable through biodegradation. A natural attenuation evaluation performed at these sites has shown that the contaminants appear to be degrading at a slow rate (ERM 2001a). This is an indication that the contaminant zone may be depleted of a growth factor as a result of past degradation of the contaminants.

Performing enhanced bioremediation involves injecting the material used to stimulate biological activity into the contaminated zone. Depending on the material used and the concentration of contaminants being treated, the material may require multiple injections to maintain optimal conditions. The two process options for this technology are enhanced aerobic bioremediation and enhanced anaerobic bioremediation.

Enhanced Aerobic Bioremediation

In scenarios where aerobic respiration is the preferred biological pathway for contaminant degradation, oxygen acts as the electron acceptor and is frequently depleted. Contaminants at IRP Sites 2, 9, and 11 that are capable of degradation by aerobic bioremediation include benzene, VC, cis-1,2-DCE, and trans-1,2-DCE. A lack of oxygen results in the use of other electron acceptors and biological pathways, which are much slower than aerobic respiration. Increasing the dissolved oxygen content in the contaminated zone ensures that aerobic respiration is the dominant biological pathway. This can be accomplished by injecting a substance that slowly releases oxygen.

One material that has been shown to be effective at treating a variety of contaminants is ORC®, produced by Regenesis. ORC® is a magnesium peroxide material that slowly releases elemental oxygen when hydrated.

A pilot test using ORC® was conducted at IRP Site 2. The purpose of the test was to evaluate the effectiveness of ORC® at reducing chlorinated VOCs in Shallow Zone groundwater and to determine a radius of influence for the injected ORC®. Significant reduction of chlorinated VOC concentrations in groundwater was observed, particularly cis-1,2-DCE and VC. Over the 3-month test duration, VC, cis-1,2-DCE, and trans-1,2-DCE were reduced by 70 to 75 percent at the furthest monitoring well, 12 feet downgradient of the injection location. Because the biological treatment of VOCs is slower than other methods, it can be assumed that the radius of influence for this test is at least 12 feet (ERM 2001c).

Enhanced Anaerobic Bioremediation

The correct oxidation-reduction state and the presence of electron donors are important factors in scenarios where reductive dechlorination is the preferred pathway for degradation of chlorinated hydrocarbons. TCE is the contaminant present at the Base that is most conducive to reductive dechlorination. Dissolved hydrogen added to source area groundwater can act as the required electron donor when others have been depleted, as well as serve to lower the redox potential to the appropriate range.

Several hydrogen sources exist that can be injected into the contaminated zone. Sodium lactate has been used successfully to enhance the biodegradation of chlorinated hydrocarbons, particularly tetrachloroethene and TCE. Sodium lactate is consumed quickly by subsurface bacteria, and as such repeated applications are required. Soybean oil has also been used as a hydrogen source for the treatment of chlorinated hydrocarbons. Soybean oil is expected to be an economical, long-lasting hydrogen source, but has not been extensively tested beyond the microcosm level. One widely used hydrogen source is a product called Hydrogen Release Compound, also produced by Regenesis. This product is a slow-releasing lactate product that has been proven effective at accelerating the biodegradation of some chlorinated hydrocarbons.

4.4.5.3 Physical Treatment

In situ physical treatment takes advantage of the physical properties of the COCs, such as volatility, and applies a technology based on this property. These technologies use processes that have traditionally been applied to extracted groundwater, such as counter-current air stripping. In-well aeration was the physical treatment process option retained for evaluation in this FS and is described below.

In-Well Aeration

In-well aeration, also known as in-well vapor stripping, is a technology for the in situ remediation of groundwater contaminated by VOCs (Ground-Water Remediation Technologies Analysis Center 1997). The in-well aeration process involves the creation of a groundwater circulation cell surrounding a well through which contaminated groundwater is cycled. The typical aeration well has hydraulically separated upper- and lower-screened intervals within the same water-bearing zone. The lower screen, through which groundwater enters, is placed at or near the bottom of the contaminated aquifer and the upper screen, through which groundwater is discharged, is installed across or above the water table.

The mechanism for aerating the groundwater varies with each particular technology. One mechanism involves sparging groundwater at the lower screen, volatilizing VOCs and causing the water to rise up an inner well casing. The water exits the top of the inner casing and flows out the upper screen in an outer well casing. Another method involves pumping the groundwater from the lower screen, air stripping the water in a small stripping tower built into the top of the well, and allowing the water to flow out the upper well screen. In both methods the discharged groundwater flows downward, eventually reaching the lower portion of the aquifer, where it is cycled back through the well into the lower screened interval.

Contaminated vapors can be drawn off above ground, or injected into the vadose zone for treatment by natural biodegradation. Vapors extracted from the well exhibiting sufficiently low VOC concentration can be discharged directly to the atmosphere. Those extracted vapor exhibiting elevated VOC concentrations, would be discharged through a catalytic oxidizer, or through activated carbon beds.

Discharging vapors through a catalytic oxidizer involves heating the vapor stream using a natural gas burner, and passing the heated vapor stream across a platinum-based catalyst, which oxidizes the VOCs into carbon dioxide, water, and in the case of chlorinated VOCs, hydrochloric acid. A scrubber can be used to remove the hydrochloric acid from the air stream if required. The air stream is then discharged to the atmosphere through a stack.

Discharging vapors through an activated carbon vessel also removes VOCs from the air stream. This is accomplished through an adsorption process. The activated carbon eventually becomes saturated and must be transported off-site for regeneration or disposal.

The effectiveness of in-well aeration is based on the ability of the contaminants to be volatilized, and the flow characteristics of the aquifer. This option is best suited for VOCs in environments that allow significant horizontal and vertical groundwater flow. The VOCs at IRP Sites 2, 9, and 11 are all readily volatilized. The Shallow Zone at these sites and the Deep Zone at IRP Sites 2 and 11 are fairly homogenous fine sand, and should be conducive to groundwater flow to the aeration well. However, this process relies on the flow of groundwater out of the upper screen at the top of the water-bearing zone being treated. Aeration wells installed in the Deep Zone would have the lower screen set just above the bottom of the Deep Zone and the upper screen set just below the floodplain silts separating the Deep Zone from the Shallow Zone. However, wells installed to treat the Shallow Zone would require that the upper screen be set in the floodplain silts above the Shallow Zone due to the shallow nature of groundwater in the Shallow Zone. The restriction of flow out of the upper screen in Shallow Zone aeration wells may limit the overall effectiveness of this alternative.

During the RI for the Portland ANGB (ERM 2001a), a treatability test was performed using in-well aeration at IRP Site 2. At the completion of this test a full 100 percent removal of all VOCs (including VC; cis- and trans-1,2-dichloroethene; and TCE) from treated groundwater was achieved at a moderate air flow. This system differed from most in-well aeration systems in that the groundwater was aerated within the well, and was pumped out for disposal rather than circulated back into the aquifer. Although this system required disposal of treated groundwater, the contaminant levels resulting from the treatment were suitable for discharge to the sanitary sewer. No indication of a radius of influence of the aeration system was observed.

4.4.5.4 Monitored Natural Attenuation

The use of MNA to achieve RAOs relies on biological, physical, and chemical processes that are naturally occurring in the environment. These processes may include biodegradation, dispersion and dilution, sorption, and volatilization. Monitoring and documenting the intrinsic bioremediation element of natural attenuation is the major focus of this alternative. MNA involves no active measures to contain or treat groundwater contaminated with VOCs.

Strategically located new monitoring wells are combined with current monitoring wells to accurately monitor the extent of each VOC plume. The groundwater would also be monitored for intrinsic bioremediation

parameters such as nitrate, sulfate, dissolved iron, methane, ethene, carbon dioxide, alkalinity, dissolved oxygen, and redox potential. These parameters measured with VOC concentrations will allow calculation of removal rates.

MNA is considered a treatment technology, as described in *Use of Monitored Natural Attenuation at Superfund, RCRA Corrective Action, and Underground Storage Tank Sites,* USEPA, OSWER Directive 9200.4-17, November 1997 (USEPA 1997).

The MNA alternative is most appropriate at sites where the following conditions exist:

1. The source of contamination to the groundwater has been removed.

2. The quantity of contaminants remaining in the environment is minor, limited in extent, and not migrating.

3. The risk to human health, safety, and the environment is insignificant.

The VOCs that make up the COCs at IRP Sites 2, 9, and 11 are all capable of natural biodegradation. However, the most widespread VOC, VC, degrades naturally at a very slow rate, and has a tendency to accumulate since it is a degradation product of the higher-order chlorinated VOCs, primarily TCE and cis-1,2-DCE, which tend to naturally degrade more quickly.

4.5 Development of Remedial Alternatives

Several of the remedial technology process options described above have been tested at the Portland ANGB, and are known to be effective at treating VOCs in groundwater. The selected process options were developed into remedial alternatives, which address the RAOs developed for the Portland ANGB. Six alternatives were developed using an appropriate combination of process options.

4.5.1 Remedial Alternative 1: No Action

This remedial alternative implements the no action process option. As discussed, the FS process requires consideration of the No Action Alternative. Under this alternative, no site modifications or groundwater monitoring would be implemented, and the engineering and institutional controls previously described would not be used.

4.5.2 Process Options Common to Alternatives 2, 3, 4, 5, and 6

Process options described under the institutional or engineering controls general response actions are included in the remaining alternatives. These process options provide protection from existing or future remaining risks at the Base. These components will be the same for each alternative, and are therefore described separately, rather than repeatedly for each alternative. The costs associated with these common tasks are not included in the cost estimates for each remedial alternative because they are common to all the alternatives (except Alternative 1) and are not specific to each IRP site. The No Action remedial alternative is the only alternative that does not include these additional components. The common tasks for each of the remaining remedial alternatives include:

- Monitoring VOCs in Shallow Zone, Deep Zone, and CRSA beyond each of the boundaries of IRP Sites 2, 9, and 11. Monitoring would be conducted annually for approximately 30 years.

- Implement Base-wide deed restrictions that limit the development of Base groundwater as a water supply.

- Implement zoning restrictions encompassing the current Base footprint that restricts rezoning of the property for uses other than industrial.

- Implement Base-wide access restrictions that prevent use of the facility by unauthorized personnel and/or for unauthorized purposes.

- Implement a Base-wide health and safety program requiring appropriate training, equipment, and monitoring during activities that put Base workers in contact with groundwater.

- Utilize alternative water supplies, such as the existing public water supply, when additional water capacity is required, rather than obtaining this capacity through extraction of groundwater at the Base.

4.5.3 Remedial Alternative 2: Monitored Natural Attenuation

Alternative 2 involves the implementation of MNA as the primary treatment method. MNA would be implemented across the full extent of each site. The duration of this alternative is expected to be approximately 30 years. This alternative also involves the implementation of the common elements described in Section 4.5.2.

Implementation of Alternative 2 at IRP Site 2 would involve:

- Performing a brief direct-push investigation to delineate the lateral extent of VOCs in Deep Zone groundwater. The concentrations of VOCs in the Deep Zone are expected to fluctuate significantly prior to the future implementation of a Deep Zone remedial action. This investigation would consist of collecting approximately 30 direct-push groundwater samples immediately prior to implementation of the remedial action.

- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and two CRSA monitoring wells within, and surrounding, the hot spot of contamination.

- Monitoring the new and existing monitoring wells quarterly for 1 year and annually for 30 years. Twenty-six wells will be monitored for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters.

Implementation of Alternative 2 at IRP Site 9 would involve:

- Installing seven Shallow Zone monitoring wells within, and surrounding, the hot spot of contamination.

- Monitoring the new and existing monitoring wells quarterly for 1 year and annually for 30 years. Ten wells will be monitored for VOC concentrations. Additionally, three of these wells will be monitored for MNA parameters.

Implementation of Alternative 2 at IRP Site 11 would involve:

- Performing a direct-push investigation immediately prior to remedial action implementation to determine the current extent of VOCs in Deep Zone groundwater similar to that described above for IRP Site 2.

- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and three CRSA monitoring wells within, and surrounding, the hot spot of contamination.

- Monitoring the new and existing monitoring wells quarterly for 1 year and annually for 30 years. Twenty-three wells will be monitored for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters.

4.5.4 Remedial Alternative 3: In Situ Oxidation-Potassium Permanganate/ Persulfate Injection with Monitored Natural Attenuation

Alternative 3 utilizes a combination of the treatment process options discussed in Section 4.4. The primary contaminant treatment within the hot spot will be performed through in situ oxidation. Because of the similarity in application technique, potassium permanganate and persulfate are interchanged in this alternative. Potassium permanganate will be used to treat chlorinated VOCs and persulfate will be used to treat benzene. MNA will be used to measure the natural degradation of low concentration contaminants immediately outside of the hot spot. The active treatment duration for this alternative is expected to be 2 years, followed by 5 years of monitoring. This treatment duration is an approximation of the expected duration required to meet the RAOs and is based on similar cases. Injection spacing used for this alternative is based on the results of the permanganate injection pilot test conducted at IRP Site 2 (ERM 2001c). This alternative also includes implementation of the common elements discussed in Section 4.5.2.

Implementation of Alternative 3 at IRP Site 2 would involve:

- Performing a direct-push investigation immediately prior to remedial action implementation to determine the current extent of VOCs in Deep Zone groundwater.

- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and two CRSA monitoring wells within, and surrounding, the hot spot of contamination;

- Injecting 35 pounds of potassium permanganate as a 2 percent water-based solution in each of numerous direct-push injection locations performed at a specific frequency. This is the expected limit of injection at a single location, per event. The locations and frequency consist of:

  – Approximately 250 injections at a 25-foot spacing within the primary treatment area injected from the bottom of the Shallow Zone up to the water table. These injections will be performed every 6 months for 2 years, resulting in four applications total. The locations will be adjusted for each application, resulting in a net spacing of approximately 12 feet.

  – Approximately 60 injections at a 25-foot spacing in the area outside of the primary treatment area but within the hot spot, injected from

the bottom of the Shallow Zone up to the water table. These injections will be performed every year for 2 years, or two injections total. The locations will be adjusted for each application, resulting in a net spacing of approximately 18 feet.

- Approximately 80 injections at a 25-foot spacing within the southeast portion of the hot spot, near the source area, injected from the bottom of the Deep Zone up to the top of the Deep Zone. These injections will be performed every 6 months for 2 years, resulting in four applications total. The locations will be adjusted for each application, resulting in a net spacing of approximately 12 feet.

- Monitoring the new and existing monitoring wells quarterly for 2 years and annually for 5 years. Twenty-six wells will be monitored for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters and potential byproducts such as chromium, cadmium, and mercury.

Implementation of Alternative 3 at IRP Site 9 would involve:

- Installing seven Shallow Zone monitoring wells within, and surrounding, the hot spot of contamination;

- Injecting iron-catalyzed sodium persulfate at approximately 50 locations on a 25-foot spacing. Approximately 95 pounds of persulfate as a 3 to 5 percent water-based solution will be injected from the bottom of the Shallow Zone up to the water table. These injections will be performed every 6 months for 2 years, resulting in four applications total. The locations will be adjusted for each application, resulting in a net spacing of approximately 12 feet.

- Monitoring the new and existing monitoring wells quarterly for 2 years and annually for 5 years. Ten wells will be monitored for VOC concentrations. Additionally, three of these wells will be monitored for MNA parameters and potential byproducts such as chromium, cadmium, and mercury.

Implementation of Alternative 3 at IRP Site 11 would involve:

- Performing a direct-push investigation immediately prior to remedial action implementation to determine the current extent of VOCs in Deep Zone groundwater.

- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and three CRSA monitoring wells within, and surrounding, the hot spot of contamination;

- Installing eight Shallow Zone horizontal injection wells and four Deep Zone horizontal injection wells within the hot spot of contamination. These wells will be placed at the approximate vertical mid-points of the Shallow Zone and Deep Zone. Horizontal injection wells were selected over vertical wells or direct-push drilling methods to prevent disturbance of flight operations or the concrete flight apron.

- Injecting potassium permanganate as a 2 percent water-based solution in each of the injection wells. Approximately 12 gallons of permanganate solution will be injected for each foot of screen length at each well. This volume meets the oxidant stoichiometric demand for the contaminants. These injections will be performed every 6 months for 2 years, resulting in a total of four applications.

- Monitoring the new and existing monitoring wells quarterly for 2 years and annually for 5 years. Twenty-three wells will be monitored for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters and potential byproducts such as chromium, cadmium, and mercury.

4.5.5 Remedial Alternative 4: In Situ Oxidation-Ozonation with Monitored Natural Attenuation

Alternative 4 also utilizes a combination of the treatment process options discussed in Section 4.4. The primary contaminant treatment within the hot spot will be performed through in situ oxidation. Ozone sparging will be used as the method of oxidation. Groundwater in the Shallow Zone and Deep Zone at IRP Sites 2 and 11 and in the Shallow Zone only at IRP Site 9 will be treated by ozone sparging. SVE will be used to collect excess ozone and any volatilized VOCs in the vadose zone and the top of the Deep Zone. MNA will be used to measure the natural degradation of low concentration contaminants immediately outside on the fringe of the hot spot. The active treatment duration for this alternative is expected to be 3 years, followed by 5 years of monitoring. This treatment duration is an approximation of the expected duration required to meet the RAOs and is based on similar cases and information from system vendors. Injection spacing used for this alternative is also based on similar cases and information from system vendors. This alternative also includes implementation of the common elements discussed in Section 4.5.2.

Implementation of Alternative 4 at IRP Site 2 would involve:

- Performing a direct-push investigation immediately prior to remedial action implementation to determine the current extent of VOCs in Deep Zone groundwater.
- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and two CRSA monitoring wells within, and surrounding, the hot spot of contamination;
- Installing 32 Shallow Zone sparging wells and 12 Deep Zone sparging wells within the hot spot of contamination;
- Installing SVE equipment and piping;
- Installing below-grade piping from each well to a common system location. Piping installation will involve trenching, laying pipe, and backfilling;
- Operating the ozone sparging system for 3 years;
- Monitoring the new and existing monitoring wells quarterly for 3 years and annually for 5 years. Twenty-six wells will be monitored for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters; and
- Quarterly air sampling of each SVE system's air effluent to assess the system performance.

Implementation of Alternative 4 at IRP Site 9 would involve:

- Installing seven Shallow Zone monitoring wells within, and surrounding, the hot spot of contamination;
- Installing 16 Shallow Zone sparging wells within the hot spot of contamination;
- Installing SVE equipment and piping;
- Installing below-grade piping from each well to a common system location. Piping installation will involve trenching, laying pipe, and backfilling;
- Operating the ozone sparging system for 3 years;

- Monitoring the new and existing monitoring wells quarterly for 3 years and annually for 5 years. Ten wells will be monitored for VOC concentrations. Additionally, three of these wells will be monitored for MNA parameters; and

- Quarterly air sampling of each SVE system's air effluent to assess the system performance.

Implementation of Alternative 4 at IRP Site 11 would involve:

- Performing a direct-push investigation immediately prior to remedial action implementation to determine the current extent of VOCs in Deep Zone groundwater.

- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and three CRSA monitoring wells within, and surrounding, the hot spot of contamination;

- Installing eight Shallow Zone horizontal ozone sparge wells and four Deep Zone horizontal ozone sparge wells within the hot spot of contamination. These wells will be placed at approximately the bottom of the Shallow Zone and Deep Zone. Horizontal injection wells were selected over vertical wells or direct-push drilling methods to prevent disturbance of flight operations or the concrete flight apron.

- Installing eight horizontal vapor extraction wells above the Shallow Zone and four horizontal vapor extraction wells at the top of the Deep Zone directly above the respective ozone sparging wells. The Deep Zone vapor extraction wells would be under saturated conditions and would serve to relieve built up gasses resulting from sparging rather than as traditional SVE wells.

- Installing SVE equipment and piping.

- Installing below-grade piping from each well to a common system location. Piping installation will involve concrete removal, trenching, laying pipe, backfilling, and resurfacing.

- Operating the ozone sparging system for 3 years;

- Monitoring the new and existing monitoring wells quarterly for 3 years and annually for 5 years. Twenty-three wells will be monitored for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters; and

- Quarterly air sampling of each system's air effluent to assess the system performance.

4.5.6 Remedial Alternative 5: Enhanced Bioremediation with Monitored Natural Attenuation

This alternative combines the use of enhanced aerobic and anaerobic bioremediation and MNA to treat the COCs. Areas impacted by TCE, such as the source area of IRP Site 2, will be treated using a hydrogen releasing material. All other areas will be treated using an oxygen releasing material.

MNA will be used to measure the natural degradation of low concentration contaminants immediately outside on the fringe of the hot spot. The active treatment duration for this alternative is expected to be 2 years, followed by 5 years of monitoring. This treatment duration is an approximation of the expected duration required to meet the RAOs and is based on similar cases and vendor information. Injection spacing used for this alternative is based on the results of the enhanced aerobic bioremediation pilot test conducted at IRP Site 2 (ERM 2001c). This alternative also includes implementation of the common elements discussed in Section 4.5.2.

Implementation of Alternative 5 at IRP Site 2 would involve:

- Performing a direct-push investigation immediately prior to remedial action implementation to determine the current extent of VOCs in Deep Zone groundwater.

- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and two CRSA monitoring wells within, and surrounding, the hot spot of contamination;

- Injecting 30 pounds of a hydrogen releasing material in approximately 10 Shallow Zone direct-push injection locations at an initial spacing of 25 feet. The injection amount may vary, based on the conductivity of the Shallow Zone soils. The material will be injected from the bottom of the Shallow Zone up to the water table. The material will be injected every 6 months for approximately 2 years, resulting in four applications total. The locations will be adjusted for each application, resulting in a net spacing of approximately 12 feet;

- Injecting 30 pounds of oxygen releasing material in each of numerous direct-push injection locations performed at a specific frequency. The locations and frequency consist of:

  – Approximately 250 injections at a 25-foot spacing within the primary treatment area injected from the bottom of the Shallow Zone up to the water table. These injections will be performed every 6 months for 2 years, resulting in four applications total. The locations will be adjusted for each application, resulting in a net spacing of approximately 12 feet.

  – Approximately 60 injections at a 25-foot spacing in the area outside of the primary treatment area but within the hot spot, injected from the bottom of the Shallow Zone up to the water table. These injections will be performed every year for 2 years, or two injections total. The locations will be adjusted for each application, resulting in a net spacing of approximately 18 feet.

  – Approximately 80 injections at a 25-foot spacing within the southeast portion of the hot spot, near the source area, injected from the bottom of the Deep Zone up to the top of the Deep Zone. These injections will be performed every 6 months for 2 years, resulting in four applications total. The locations will be adjusted for each application, resulting in a net spacing of approximately 12 feet.

- Monitoring the new and existing monitoring wells quarterly for 2 years and annually for 5 years. Twenty-six wells will be monitored for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters.

Implementation of Alternative 5 at IRP Site 9 would involve:

- Installing seven Shallow Zone monitoring wells within, and surrounding, the hot spot of contamination;

- Injecting 30 pounds of an oxygen releasing material in approximately 50 Shallow Zone direct-push injection locations at an initial spacing of 25 feet. The material will be injected from the bottom of the Shallow Zone up to the water table. The material will be injected every 6 months for approximately 2 years, resulting in four applications total. The locations will be adjusted for each application, resulting in a net spacing of approximately 12 feet; and

- Monitoring the new and existing monitoring wells quarterly for 2 years and annually for 5 years. Ten wells will be monitored for VOC concentrations. Additionally, three of these wells will be monitored for MNA parameters.

Implementation of Alternative 5 at IRP Site 11 would involve:

- Performing a direct-push investigation immediately prior to remedial action implementation to determine the current extent of VOCs in Deep Zone groundwater.

- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and three CRSA monitoring wells within, and surrounding, the hot spot of contamination.

- Injecting 30 pounds of oxygen releasing material in each of numerous direct-push injection locations performed at a specific frequency. The locations and frequency consist of:

  - Approximately 270 injections at a 25-foot spacing within the primary treatment area injected from the bottom of the Shallow Zone up to the water table. These injections will be performed every 6 months for 2 years, resulting in four applications total. The locations will be adjusted for each application, resulting in a net spacing of approximately 12 feet.

  - Approximately 70 injections at a 25-foot spacing in the area outside of the primary treatment area but within the hot spot, injected from the bottom of the Shallow Zone up to the water table. These injections will be performed every year for 2 years, or two injections total. The locations will be adjusted for each application, resulting in a net spacing of approximately 18 feet.

  - Approximately 90 injections at a 25-foot spacing within the southeast portion of the hot spot, near the source area, injected from the bottom of the Deep Zone up to the top of the Deep Zone. These injections will be performed every 6 months for 2 years, resulting in four applications total. The locations will be adjusted for each application, resulting in a net spacing of approximately 12 feet.

- Coring and repair of the flight apron concrete in accordance with ANG specifications will be required at approximately 75 percent of the direct-push injection locations.

- Monitoring the new and existing monitoring wells quarterly for 2 years and annually for 5 years. Twenty-three wells will be monitored for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters.

4.5.7 Remedial Alternative 6: In-Well Aeration with Monitored Natural Attenuation

Alternative 6 also utilizes a combination of the treatment process options discussed in Section 4.4. The primary contaminant treatment within the hot spot will be performed through in-well aeration. Groundwater in the Shallow Zone and Deep Zone at IRP Sites 2 and 11 and in the Shallow Zone only at IRP Site 9 will be treated. Effluent air will be treated using granular activated carbon. MNA will be used to measure the natural degradation of low concentration contaminants immediately outside of the hot spot. The active treatment duration for this alternative is expected to be 3 years, followed by 5 years of monitoring. This treatment duration is an approximation of the expected duration required to meet the RAOs and is based on information from vendors. Injection spacing used for this alternative is also based on vendor information. This alternative also includes implementation of the common elements discussed in Section 4.5.2.

Implementation of Alternative 6 at IRP Site 2 would involve:

- Performing a direct-push investigation immediately prior to remedial action implementation to determine the current extent of VOCs in Deep Zone groundwater.

- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and two CRSA monitoring wells within, and surrounding, the hot spot of contamination;

- Installing 21 Shallow Zone aeration wells and 5 Deep Zone aeration wells within the hot spot of contamination;

- Installing below-grade piping from each aeration well to a common system location. Piping installation will involve trenching, laying pipe, and backfilling;

- Operating the system for 3 years;

- Monitoring the new and existing monitoring wells quarterly for 3 years and annually for 5 years. Twenty-six wells will be monitored

for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters; and

- Quarterly air sampling of each system's air effluent to assess the system performance.

Implementation of Alternative 6 at IRP Site 9 would involve:

- Installing seven Shallow Zone monitoring wells within, and surrounding, the hot spot of contamination;

- Installing four Shallow Zone aeration wells within the hot spot of contamination;

- Installing below-grade piping from each well to a common system location. Piping installation will involve trenching, laying pipe, and backfilling;

- Operating the system for 3 years;

- Monitoring the new and existing monitoring wells quarterly for 3 years and annually for 5 years. Ten wells will be monitored for VOC concentrations. Additionally, three of these wells will be monitored for MNA parameters; and

- Quarterly air sampling of each system's air effluent to assess the system performance.

Implementation of Alternative 6 at IRP Site 11 would involve:

- Performing a direct-push investigation immediately prior to remedial action implementation to determine the current extent of VOCs in Deep Zone groundwater.

- Installing four Shallow Zone monitoring wells, two Deep Zone monitoring wells, and three CRSA monitoring wells within, and surrounding, the hot spot of contamination;

- Installing 26 Shallow Zone aeration wells and seven Deep Zone aeration wells within the hot spot of contamination. For cost estimating purposes, it is assumed that 75 percent of the wells will be installed within the flight apron concrete at IRP Site 11, and will require concrete coring and completion in accordance with ANG specifications;

- Installing below-grade piping from each well to a common system location. Piping installation will involve concrete removal, trenching, laying pipe, backfilling, and resurfacing;

- Operating the system for 3 years;

- Monitoring the new and existing monitoring wells quarterly for 3 years and annually for 5 years. Twenty-three wells will be monitored for VOC concentrations. Additionally, 10 of these wells will be monitored for MNA parameters; and

- Quarterly air sampling of each system's air effluent to assess the system performance.

SECTION 5.0

DETAILED ANALYSIS OF ALTERNATIVES

This section presents a detailed evaluation of RA alternatives. First, the evaluation criteria set forth in *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (USEPA 1988) are described. Subsequently, as outlined in the Oregon Guidance for Conducting Feasibility Studies (ODEQ 1998b), elements used to compare RA alternatives are presented. Next, the remedial alternatives described in Section 4.0 for IRP Sites 2, 9, and 11 are evaluated with respect to the criteria. Finally, the alternatives for each of the sites are collectively evaluated through a comparative analysis based on the criteria. Table 5-1 summarizes the results of this evaluation and the comparative analysis of the remedial alternatives for IRP Sites 2, 9, and 11.

5.1 Assessment Criteria

The following sections describe the elements of the nine criteria used for detailed analysis of remedial alternatives.

5.1.1 Overall Protection of Human Health and the Environment

This evaluation criterion provides a final check to assess whether each alternative provides adequate protection of human health and the environment. The overall assessment of protection considers the assessments conducted under other evaluation criteria, particularly long-term effectiveness and permanence, short-term effectiveness, and compliance with ARARs. This evaluation also allows for consideration of whether an alternative poses any unacceptable short-term or crossmedia impacts.

Oregon's Environmental Cleanup Law uses a Residual Risk Assessment (RRA) to demonstrate protectiveness. For RAs consisting solely of treatment, the RRA provides only the quantitative assessment of the risk from treatment residuals or untreated wastes remaining at the site.

TABLE 5-1

Alternatives Evaluation Summary Table
142nd FW, Portland ANGB, Portland, Oregon

IRP Site	Remedial Alternative	Evaluation Criteria									Comparative Ranking
		Overall Protection of Human Health and Environment	Compliance with ARARs	Long-Term Effectiveness and Permanence	Reduction of TMV Through Treatment	Short-Term Effectiveness	Implementability	Cost	Cost Reasonableness	Treatment of Hot Spots	
2	1. No Action	Low	Low	Low	Low	Low	High	$0	Low	Low	6
	2. Monitored Natural Attenuation (MNA)	Low	Low	Low	Low	Low	High	$717,000	Low	Low	5
	3. In-situ Oxidation-Potassium Permanganate Injection w/ MNA	High	High	High	High	Medium	High	$2,301,000	High	High	1
	4. In-Situ Oxidation – Ozonation w/ MNA	High	High	High	High	Medium	Medium	$3,501,000	Medium	High	2
	5. Enhanced Bioremediation w/ MNA	Medium	Medium	Medium	Medium	Medium	High	$2,780,000	Medium	Medium	4
	6. In-Well Aeration w/ MNA	Medium	High	High	High	Medium	Medium	$3,721,000	Medium	High	3
9	1. No Action	Low	Low	Low	Low	Low	High	$0	Low	Low	6
	2. Monitored Natural Attenuation (MNA)	Low	Low	Low	Low	Low	High	$292,000	Low	Low	5
	3. In-situ Oxidation-Sodium Persulfate Injection w/ MNA	High	High	High	High	Medium	High	$573,000	High	High	1

NOTES:
The assessment of the degree to which an alternative meets the requirements of the individual balancing factors is presented as low, medium, or high.
The six remedial alternatives for each site are then ranked from 1 (highest) to 6 (lowest) based on the overall results of this assessment.

5.1.2 Compliance with ARARs

This evaluation criterion is used to determine whether each alternative will meet all of its identified federal and state ARARs.

5.1.3 Long-Term Effectiveness and Permanence

The evaluation of a remedial alternative relative to its long-term effectiveness and permanence is made considering the risks remaining at the site after the remedial goals have been met. The assessment of long-term effectiveness is made considering the following four major factors:

- Magnitude of residual risk to human and environmental receptors remaining from untreated waste or treatment residues at the completion of remedial activities;
- Assessment of the type, degree, and adequacy of long-term management required for untreated waste or treatment residues remaining at the site;
- Assessment of the long-term reliability of engineering and/or institutional controls to provide continued protection from untreated waste or treatment residues; and
- Potential need for replacement of the remedy, and the continuing need for repairs to maintain the performance of the remedy.

Some of the criteria of Oregon's Environmental Cleanup Law Effectiveness Balancing Factor, and all of the criteria developed for the Long-Term Reliability Balancing Factor, correspond to the criteria described above.

5.1.4 Reduction of Toxicity, Mobility, or Volume through Treatment

This evaluation criterion addresses the degree to which RAs employ treatment technologies that permanently and significantly reduce the toxicity, mobility, or volume (TMV) of the hazardous substance(s). The evaluation considers the following factors:

- Treatment processes;
- Amount of hazardous materials that will be treated;

- Degree of expected reduction in TMV, including how the principal threat is addressed through treatment;
- Degree to which the treatment will be irreversible; and
- Type and quantity of treatment residuals that will remain following treatment.

Some of the criteria of the Effectiveness Balancing Factor developed in Oregon's Environmental Cleanup Law correspond to the above USEPA criteria.

5.1.5 Short-Term Effectiveness

The short-term effectiveness of a remedial alternative is evaluated relative to its effect on human health and the environment during implementation of the RA. The short-term effectiveness is assessed based on the following factors:

- Short-term risks that might be posed to the community during implementation of an alternative;
- Potential impacts on workers during RA, and the effectiveness and reliability of protective measures;
- Potential environmental impacts of the RA, and the effectiveness and reliability of mitigative measures during implementation; and
- Length of time required to achieve RAOs.

The criteria listed above correspond with the criteria used to assess the Implementation Risk Balancing Factor developed in Oregon's Environmental Cleanup Law.

5.1.6 Implementability

The remedial alternatives must be evaluated to estimate the degree to which each can satisfy implementability criteria. Implementability refers to the technical, administrative, and environmental feasibility of implementing an alternative, and the availability of various materials and services required during its implementation.

The USEPA Implementability definition generally corresponds to that specified by Oregon's Environmental Cleanup Law. However, as

summarized below, Oregon defines criteria by which Implementability is measured:

- Practical, technical, and legal difficulties and unknowns associated with the construction and implementation of a technology, engineering control, or institutional control, including potential scheduling delays;
- The ability to monitor the effectiveness of the remedy;
- Consistency with federal, state and local requirements; activities needed to coordinate with other agencies; and the ability and time required to obtain any necessary authorization from other governmental bodies;
- Availability of necessary services, materials, equipment, and specialists, including the availability of adequate off-site treatment, storage, and disposal capacity and services, and availability of prospective technologies; and
- Any other information relevant to implementability.

5.1.7 Cost

A detailed cost estimate was developed for each remedial alternative in accordance with the Remedial Action Costing Procedures Manual (USEPA 1985). These cost estimates are presented in Appendix B. Costs are based on conceptual design, and are expressed in terms of year 2000 dollars.

The Reasonableness of Cost Balancing Factor specified by Oregon's Environmental Cleanup Law provides additional requirements that must be evaluated. These criteria are:

- Cost of the RA including:
  - Capital costs, including both direct and indirect costs;
  - Annual operation and maintenance (O&M) costs;
  - Costs of any periodic review requirements; and
  - Net present value of all of the above.

- Degree to which the costs of the RA are proportionate to the benefits to human health and the environment created through risk reduction or risk management;

- With respect to hot spots of contamination in water, the degree to which the costs of the RA are proportionate to the benefits created through restoration or protection of existing and reasonably likely future beneficial uses of water;

- The degree of sensitivity and uncertainty of the costs; and

- Any other information relevant to cost-reasonableness.

5.1.8 State Acceptance

This criterion evaluates the technical and administrative issues and concerns the ODEQ may have regarding each of the alternatives.

5.1.9 Community Acceptance

This criterion evaluates technical and administrative issues and concerns the public may have regarding each of the alternatives.

5.1.10 Treatment of Hot Spots

For hot spots in groundwater, the FS must evaluate the feasibility of treatment to levels that will no longer produce significant adverse effects on the beneficial uses of the water. This criterion evaluates the ability of an alternative to meet the requirement to treat contaminated groundwater to below significant, adverse-effect levels.

5.2 IRP Site 2

5.2.1 IRP Site 2 - Individual Analysis of Alternatives

The following presents an evaluation of the RA alternatives for IRP Site 2 against the evaluation criteria. The remedial alternatives evaluated for IRP Site 2 include:

- Alternative 1: No Action

- Alternative 2: MNA
- Alternative 3: In Situ Oxidation – Potassium Permanganate Injection with MNA
- Alternative 4: In Situ Oxidation – Ozone Sparging with MNA
- Alternative 5: Enhanced Bioremediation with MNA
- Alternative 6: In-Well Aeration with MNA

5.2.1.1 IRP Site 2 - Alternative 1: No Action

The following is an evaluation of the application of Alternative 1 at IRP Site 2 with respect to the criteria described in Section 5.1.

Overall Protection of Human Health and Environment. The No Action Alternative would not be protective of human health and the environment in the short-term, because the risks associated with site groundwater would not immediately be reduced, either by treatment or by implementing restrictions that would prevent exposure site groundwater, such as institutional controls. Because contaminated Shallow Zone and Deep Zone groundwater has the potential to migrate off-site, the No Action Alternative would not provide long-term protection of human health and the environment.

Compliance with ARARs. The No Action Alternative does not meet chemical-specific ARARs because several chlorinated VOCs in Shallow Zone groundwater and VC in Deep Zone groundwater currently exceed ARARs. The No Action Alternative would potentially reduce VOC concentrations to below respective ARARs in downgradient areas of IRP Site 2 due to natural processes. However, the higher concentration VOCs in the upgradient area of IRP Site 2 are not expected to naturally degrade to below ARARs within a reasonable timeframe.

Long-Term Effectiveness and Permanence. The No Action Alternative will not provide long-term effectiveness and permanence because a residual risk to human and environmental receptors remaining from untreated chlorinated VOCs in Shallow Zone and Deep Zone groundwater exists.

Reduction of TMV through Treatment. The No Action Alternative does not include any treatment to reduce TMV. As a result, it is possible that chlorinated VOCs would continue to migrate laterally and vertically and

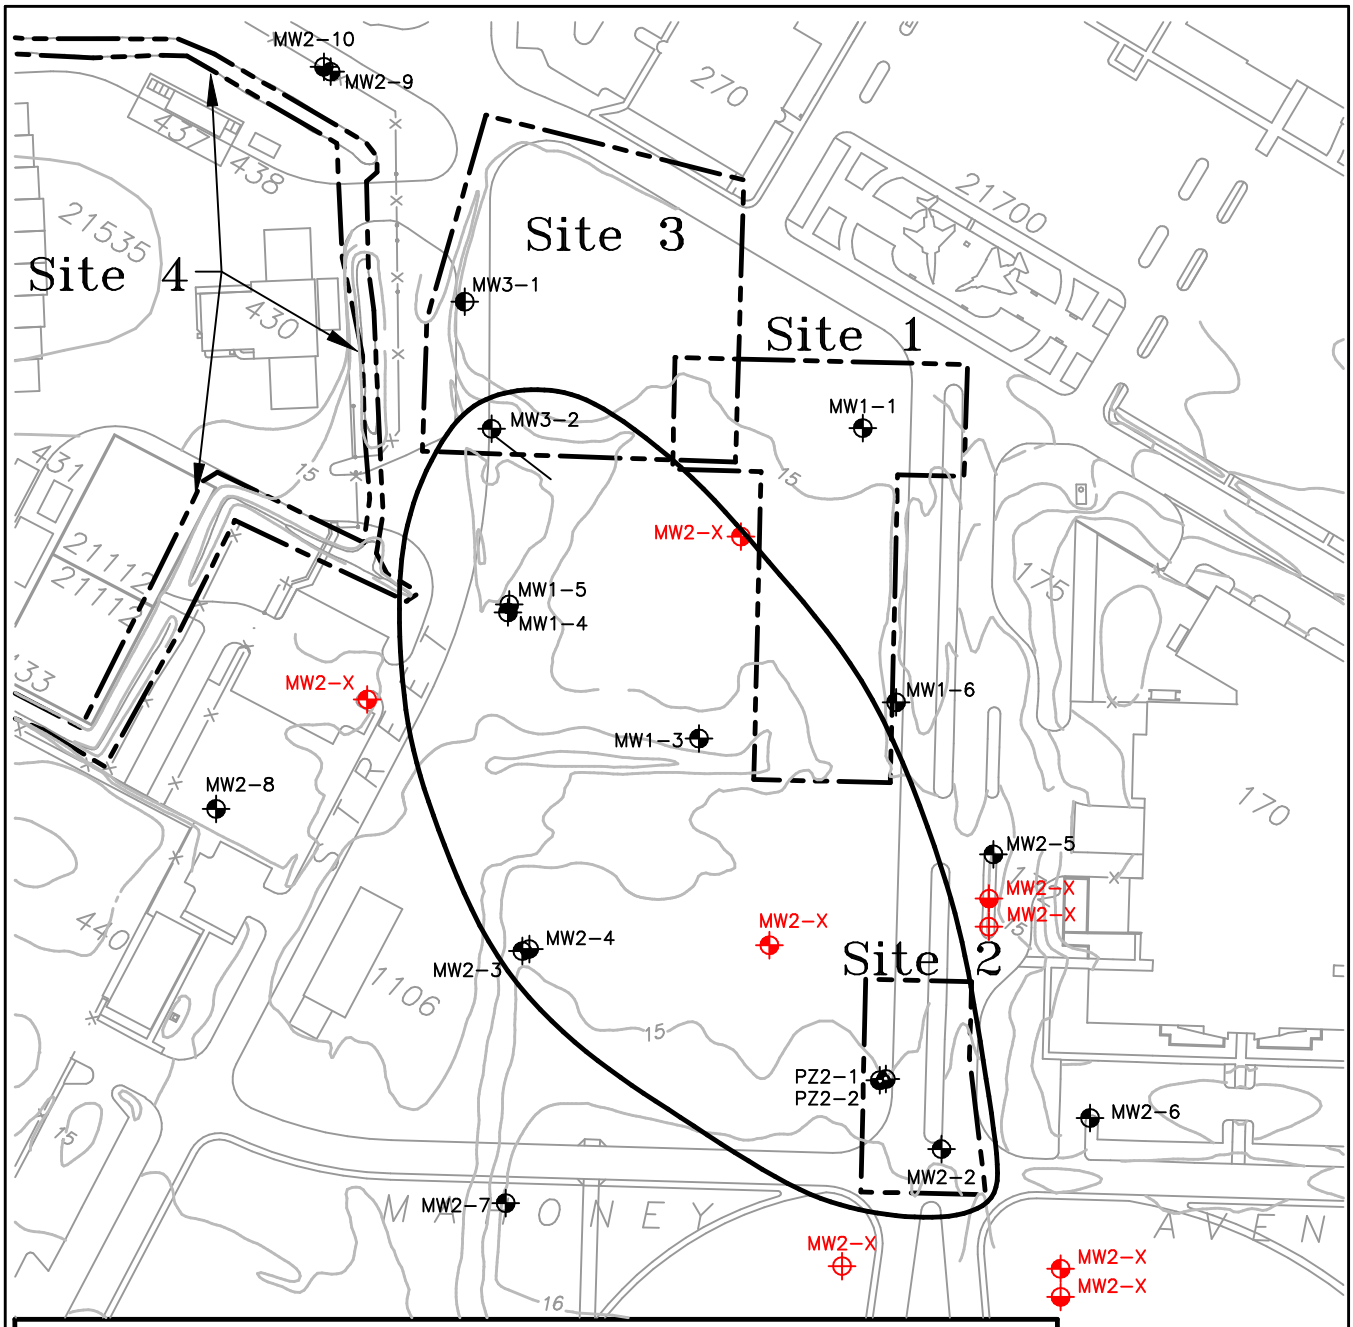
eventually reach off-site receptors. Biodegradation of TCE in Shallow Zone groundwater may continue to occur as observed in the past, but the natural degradation of lower-order chlorinated ethenes (cis- and trans-1,2-DCE and VC) in the Shallow Zone and Deep Zone is not expected to be significant. The degradation is expected to be slower than migration, thereby increasing the volume of contaminated groundwater.

Short-Term Effectiveness. The No Action Alternative would present short-term human health risks associated with chlorinated VOCs in groundwater at IRP Site 2. However, these risks are no greater than the existing risks at the site.

Implementability. The No Action Alternative would not incur implementation obstacles. In addition, there are no operations and maintenance requirements for the alternative.

Cost. No costs would be associated with implementing the No Action Alternative. Because this alternative is not effective in meeting the RAOs for the site, and is therefore not protective, it has a low degree of cost reasonableness.

Treatment of Hot Spots. The No Action Alternative does not meet Oregon's requirement that hot spots in water be treated to below the significant adverse-effect level.



State Acceptance. The No Action Alternative would not be acceptable to ODEQ. Oregon requires that hot spots such as that present in groundwater at IRP Site 2 be treated to below the significant adverse-effect level.

Community Acceptance. The No Action Alternative is not expected to be acceptable to the community. The community is active at the Base in the form of a Restoration Advisory Board (RAB), and would not be accepting of leaving an area of groundwater impacted at the level of IRP Site 2 untreated.

5.2.1.2 IRP Site 2 - Alternative 2: Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 2 at IRP Site 2 with respect to the criteria described in Section 5.1. Figure 5-1 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. The MNA Alternative would be protective of human health and the environment in

ERM

IRP SITE 2

ALTERNATIVE 2
MONITORED NATURAL ATTENUATION
LOCATION OF MONITORING WELLS

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-1

G:\\6049\71
60497150.dwg, 07/06/01

the short term. Near-future exposure to groundwater with unacceptable risk is prevented through institutional and engineering controls implemented at the Base. Groundwater with VOC concentrations above unacceptable risk levels has not migrated to any off-site receptors, and is not expected to do so in the near future. However, there is long-term risk associated with off-site migration of groundwater containing VOCs. During the Natural Attenuation Evaluation conducted as part of the RI (ERM 2001a), it was concluded that the degradation rate of VC is very slow. Because of this, it is possible that Shallow Zone and Deep Zone groundwater containing levels of VC above the RAOs has the potential to migrate off-site. The MNA Alternative, therefore, would not provide long-term protection of human health and the environment.

Compliance with ARARs. The MNA Alternative does not meet chemical-specific ARARs. Several chlorinated VOCs in Shallow Zone and Deep Zone groundwater currently exceed ARARs, and are not expected to naturally degrade to below levels determined by the chemical-specific ARARs within a reasonable timeframe compared to the time frames offered by other methods.

Long-Term Effectiveness and Permanence. The MNA Alternative may provide long-term effectiveness and permanence due to eventual natural degradation of VOCs below RAOs. However, this is unlikely to occur within a reasonable time period. It is uncertain if this alternative will treat groundwater to appropriate levels prior to migrating off-site, thereby violating the first RAO.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV through Treatment. The MNA Alternative is not expected to significantly reduce the TMV of VOCs at IRP Site 2 within a reasonable timeframe. Biodegradation of TCE in Shallow Zone groundwater may continue to occur as observed in the past, but the natural degradation of lower-order chlorinated ethenes such as cis-1,2-DCE and VC in Shallow Zone and Deep Zone groundwater is not expected to occur rapidly. As such, the toxicity of groundwater may be slowly reduced. As VC is produced through reductive dechlorination of TCE and dichloroethene, the mobility will actually increase due to the increased solubility and decreased sorption tendency of VC in relation to

its parent compounds. The volume of contaminated groundwater may actually increase due to potential further downgradient and vertical migration of slowly degrading VOCs, particularly VC.

Short-Term Effectiveness. The MNA Alternative would present short-term human health risks associated with chlorinated VOCs in groundwater at IRP Site 2. The short-term risks associated with this alternative are a result of the expected duration required to meet treatment objectives. The required duration of MNA could exceed 30 years. Within that period, groundwater containing unacceptable concentrations of VOCs may migrate off-site, violating the first RAO and presenting risk to off-site receptors.

The institutional and engineering controls implemented under this alternative are expected to prevent unacceptable risk to on-site receptors, including Base workers and other workers implementing this RA.

Implementability. The MNA Alternative would not present implementation obstacles. The additional proposed wells will ensure the ability to monitor the effectiveness of this alternative, and the required technologies used for this alternative are readily available and implementable.

Cost. Capital and O&M costs associated with Alternative 2 are summarized in Table B-2, and detailed in Table B-3. Direct and indirect capital costs for this alternative are estimated to be $116,100, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first year is estimated to be $110,000, which assumes quarterly groundwater sampling. The O&M cost for the following 30 years is estimated to be $27,500 per year, which assumes annual groundwater sampling. The net present value of 31 years of O&M costs is $434,800, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 2, including a 30 percent contingency, is $717,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Because Alternative 2 does not meet the RAOs for the site within a reasonable time period, this alternative is not protective, and therefore has a low degree of cost reasonableness.

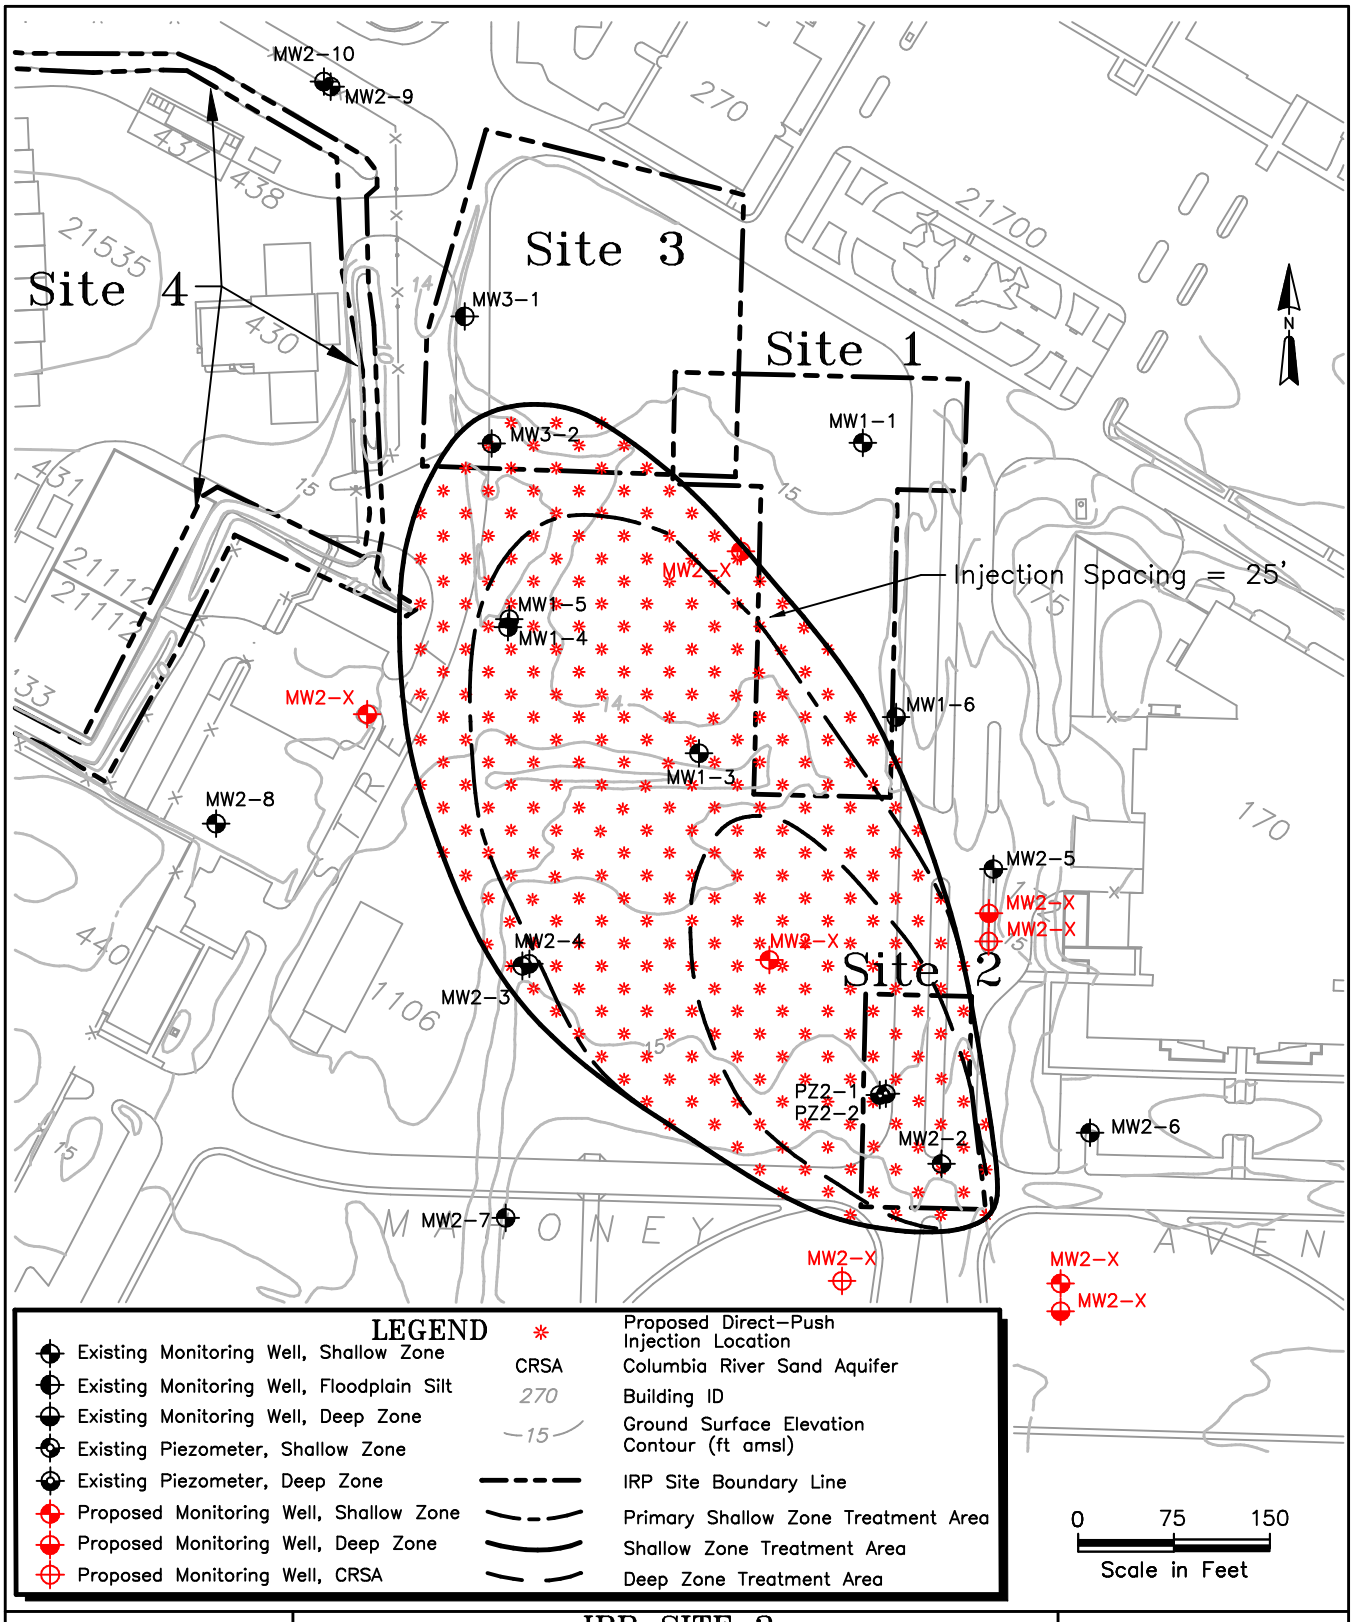
Treatment of Hot Spots. Although MNA is considered a treatment technology by the State of Oregon, the hot spot at IRP Site 2 is not

expected to be treated to concentrations below the significant adverse-effect level in a timely manner under this alternative. The hot spot, defined by the extent of contaminants above respective significant adverse-effect levels, could potentially expand due to migration of the source area.

State Acceptance. The Natural Attenuation Alternative would not be expected to be acceptable to ODEQ. Oregon requires that hot spots such as that present in groundwater at IRP Site 2 be treated within a reasonable timeframe and this is not expected to occur using the Natural Attenuation alternative.

Community Acceptance. The Natural Attenuation Alternative is not expected to be acceptable to the community due to the expected duration required to meet treatment goals.

5.2.1.3 IRP Site 2 - Alternative 3: In Situ Oxidation - Potassium Permanganate Injection with Monitored Natural Attenuation



The following is an evaluation of the application of Alternative 3 at IRP Site 2 with respect to the criteria described in Section 5.1. Figure 5-2 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative is expected to effectively remove or significantly reduce the concentrations of VOCs from Shallow Zone and Deep Zone groundwater at IRP Site 2. The risks associated with exposure to these compounds would be reduced to an acceptable level based on the current and future land use.

Compliance with ARARs. This alternative is expected to effectively reduce the concentrations of VOCs in groundwater to below the levels set by chemical-specific ARARs. Any injection activities must be coordinated through the Oregon UIC program described in Section 4.1.3.6. Compliance with this program is expected to be achievable through registration, monitoring, and reporting.

Long-Term Effectiveness and Permanence. The residual risk posed by groundwater at IRP Site 2 would be reduced by this alternative because the contaminants associated with the risks are destroyed. Groundwater monitoring would be required for an extended period after the completion of this alternative in order to verify attainment of the RAOs.

The contaminants in the downgradient areas of the site treated by MNA are expected to be destroyed within a reasonable time frame, due to

PLAN VIEW OF TREATMENT SYSTEM LAYOUT

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-2

G:\\6049\71
60497151.dwg, 07/06/01

enhanced conditions from upgradient permanganate injection. However, if long-term monitoring indicates that VOCs in this area are not degrading at an acceptable rate, potassium permanganate will be injected in this area.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant if the ownership or leaseholder of the Base property changes.

Reduction of TMV through Treatment. The use of potassium permanganate oxidation and MNA to treat VOCs in Shallow Zone and Deep Zone groundwater will result in reduced toxicity, mobility, and volume of hazardous materials in IRP Site 2 groundwater. This reduction is performed through chemical and biological destruction rather than transfer of contaminants from one media to another. The treatment process is irreversible and will result in the production of only harmless byproducts.

Short-Term Effectiveness. Workers performing the injection will be in contact with potassium permanganate in solid or dissolved form. Worker exposure would be minimized by the use of appropriate health and safety personal protective equipment.

Adverse effects on groundwater that is used for drinking or irrigation is not expected. The oxidative effects of the potassium permanganate will diminish with time as it reacts with organic material in the subsurface. As described in Section 4.4.5.1, other water quality effects are not expected to be significant enough to reach nearby receptors. Groundwater in the treatment area will be impacted by dilute potassium permanganate, requiring consideration if Base workers expect to come into contact with groundwater within the treatment area.

Risks associated with VOCs in groundwater are quickly reduced due to the rapid treatment resulting from permanganate oxidation. Destruction of VOCs in areas treated by potassium permanganate is expected to be complete within 1 to 2 years.

Implementability. The implementability of this alternative may be inhibited by the geology at the site. Preferential flow paths and areas of low conductivity will dictate where the injected potassium permanganate will flow. This may result in small regions of an aquifer not receiving

injected material. This can be overcome by reducing the grid spacing for the direct-push injection and staggering the locations of later injections.

The injection of potassium permanganate will require coordination with the ODEQ UIC program. This will create scheduling delays due to ODEQ review and public participation requirements.

The technical aspects of the actual direct-push injection of potassium permanganate are simple and should not be constrained.

Cost. Capital and O&M costs associated with Alternative 3 are summarized in Table B-2 and detailed in Table B-4. Direct and indirect capital costs for this alternative are estimated to be $1,438,550, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 2 years is estimated to be $220,000, which assumes quarterly groundwater sampling. The O&M cost for the following 5 years is estimated to be $27,500 per year, which assumes annual groundwater sampling. The net present value of 7 years of O&M costs is $331,300, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 3, including a 30 percent contingency, is $2,301,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Alternative 3 is the least expensive of the alternatives that employ active remedial measures. Additionally, this alternative is expected to meet the RAOs for the site within a reasonable time period and is thus protective. As a result, this alternative has a high degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat the VOCs in Shallow Zone and Deep Zone groundwater at IRP Site 2 to below significant adverse effect levels within a reasonable timeframe.

State Acceptance. The use of potassium permanganate to treat groundwater at the Base has been accepted by ODEQ for relatively small-scale implementation and is expected to be acceptable for full-scale application. However, ODEQ approval of larger scale use of potassium permanganate injection is likely to be contingent on an appropriate monitoring and reporting plan to ensure compliance with the UIC program.

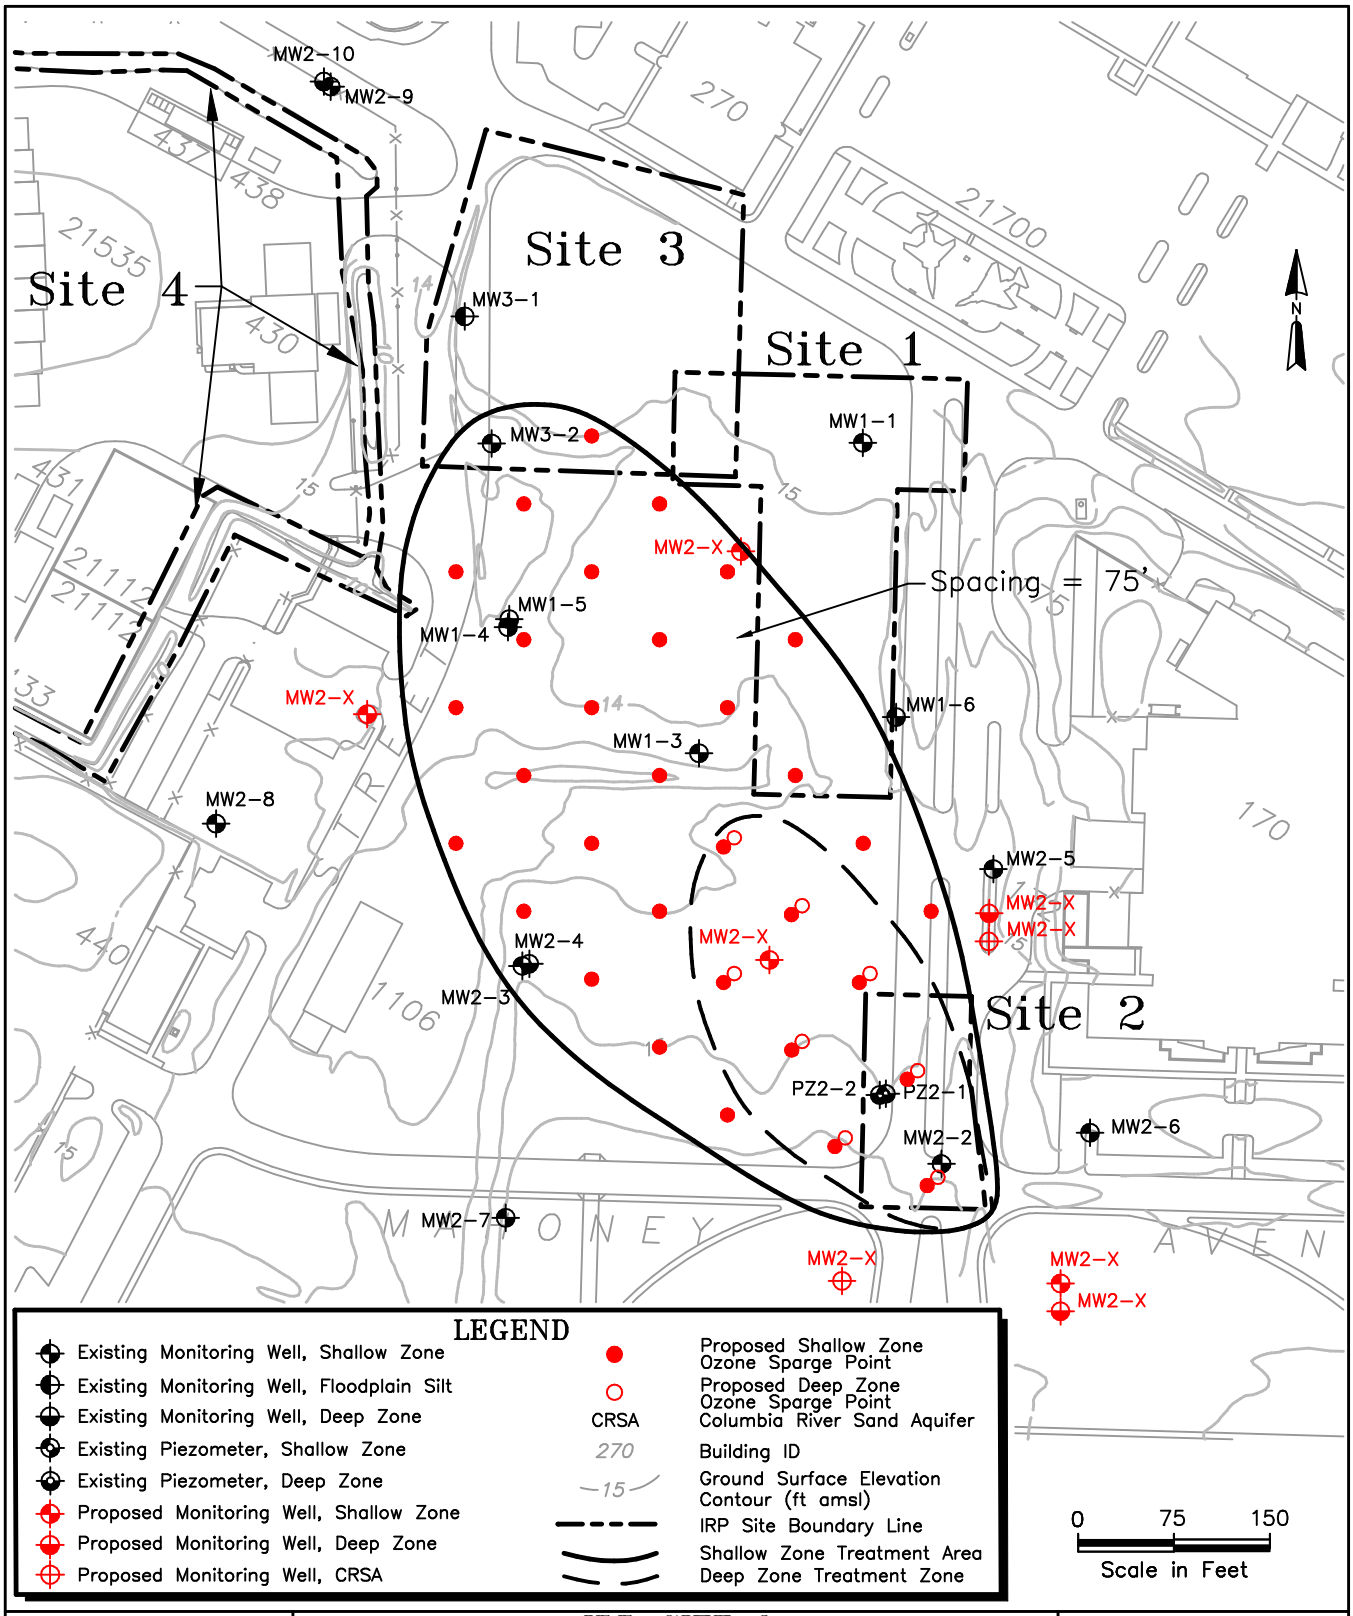
Community Acceptance. The use of potassium permanganate is expected to have some community resistance since it relies on the injection of a

foreign material into the groundwater and the perception that it will cause groundwater flowing away from the site to remain purple. An appropriate monitoring and reporting system is an important component of this alternative to allow the public the opportunity to monitor water quality during the remedial action.

5.2.1.4 IRP Site 2 - Alternative 4: In Situ Oxidation - Ozonation with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 4 at IRP Site 2 with respect to the criteria described in Section 5.1. Figure 5-3 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative is expected to effectively remove or significantly reduce the concentrations of VOCs from Shallow Zone and Deep Zone groundwater at IRP Site 2. The risks associated with exposure to these compounds would be reduced to an acceptable level based on the current and future land use.



Compliance with ARARs. This alternative is expected to effectively reduce the concentrations of VOCs in Shallow Zone and Deep Zone groundwater to below the levels set by chemical-specific ARARs. Any injection activities must be coordinated through the Oregon UIC program described in Section 4.1.3.6. Compliance with this program is expected to be achievable through registration, monitoring, and reporting.

Long-Term Effectiveness and Permanence. The residual risk posed by groundwater at IRP Site 2 would be reduced by this alternative because the contaminants associated with the risks are destroyed. Groundwater monitoring would be required for an extended period after the completion of this alternative in order to verify attainment of the RAOs.

The contaminants in the downgradient areas of the site treated by MNA are expected to be destroyed within a reasonable time frame, due to enhanced conditions from upgradient ozonation.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant if the ownership or leaseholder of the Base property changes.

Reduction of TMV Through Treatment. The use of ozonation and MNA to treat VOCs in groundwater will result in reduced toxicity, mobility, and

FIGURE 5–3

G:\\6049\71
60497152.dwg, 07/06/01

volume of hazardous materials in IRP Site 2 Shallow Zone and Deep Zone groundwater. This reduction is performed through chemical and biological destruction rather than transfer of contaminants from one media to another. The treatment process is irreversible and will result in the production of only harmless byproducts.

Short-Term Effectiveness. Ozone is a strong oxidant and care must be taken to prevent worker or base employee exposure to ozone generated for injection. This would include periodic monitoring of ozone in workspace air and enclosing and locking the ozone generator and sparge wellheads to prevent tampering.

Adverse effects on groundwater that is used for drinking or irrigation is not expected. The oxidative effects of ozone are short lived in groundwater. As described in Section 4.4.5.1, other water quality effects are not expected to be significant enough to reach nearby receptors.

Risks associated with VOCs in groundwater are quickly reduced due to the rapid treatment resulting from ozonation. Destruction of VOCs in areas treated by ozonation is expected to be complete within 3 years.

Implementability. Implementability issues identified for the installation of this alternative include installation of sub-grade piping across base roads, if necessary, avoidance of underground utilities, and connection to base utilities.

The implementability of this alternative may be inhibited by the geology at the site. Preferential flow paths and areas of low conductivity will dictate where sparged air will flow. This can usually be overcome by utilizing a pulsed sparging technique consisting of alternating periods of sparging and rest.

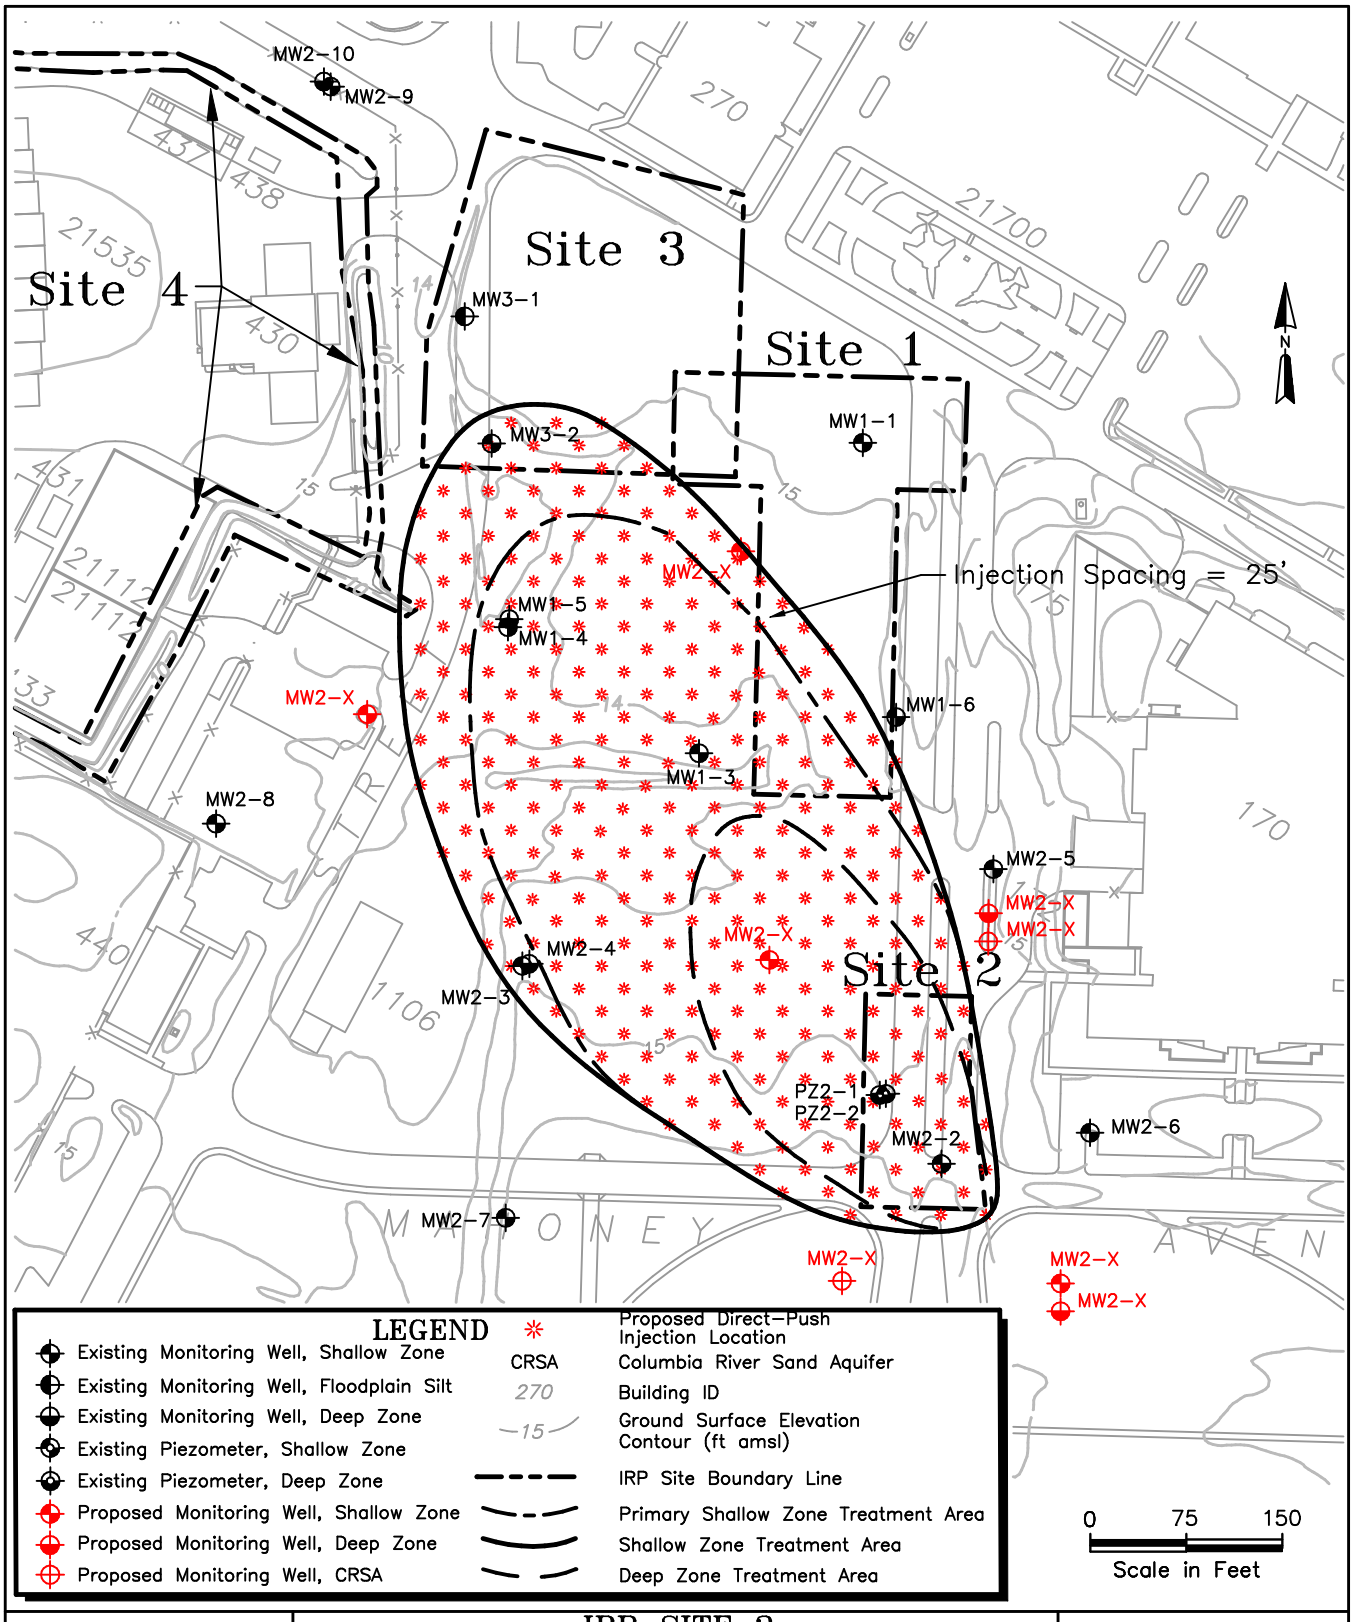
The injection of ozone will require coordination with the ODEQ UIC program. This will create scheduling delays due to ODEQ review and public participation requirements.

Cost. Capital and O&M costs associated with Alternative 4 are summarized in Table B-2 and detailed in Table B-5. Direct and indirect capital costs for this alternative are estimated to be $1,940,750, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 3 years is estimated to be $639,300, which assumes quarterly groundwater sampling and 3 years of treatment system operation. The O&M cost for the following 5 years is estimated to be $27,500 per year,

which assumes annual groundwater sampling. The net present value of 8 years of O&M costs is $752,100, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 4, including a 30 percent contingency, is $3,501,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to -30 percent.

Alternative 4 is expected to meet the RAOs for the site within a reasonable timeframe, and is thus protective. However, Alternative 4 is one of the most expensive of all the alternatives, therefore, it has a mid-range degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat the VOCs in Shallow Zone and Deep Zone groundwater at IRP Site 2 to below significant adverse-effect levels within a reasonable timeframe.



State Acceptance. The use of ozonation to treat groundwater at the Base has been accepted by ODEQ for relatively small-scale implementation and is expected to be acceptable for full-scale application. However, ODEQ approval of larger scale use of an injection technology is likely to be contingent on an appropriate monitoring and reporting plan to ensure compliance with the UIC program.

Community Acceptance. The use of ozonation is expected to have less community resistance than other injection technologies since it relies on the injection of a short-lived gas rather than a liquid. However, an appropriate monitoring and reporting system is still an important component of this alternative to allow the public the opportunity to monitor water quality during the remedial action.

5.2.1.5 IRP Site 2 - Alternative 5: Enhanced Bioremediation with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 5 at IRP Site 2 with respect to the criteria described in Section 5.1. Figure 5-4 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative is expected to effectively reduce VOCs in Shallow Zone and Deep Zone groundwater at IRP Site 2, as well as the risks associated with exposure to this contamination. However, the effectiveness of this alternative is uncertain, primarily because the use of oxygen releasing materials to treat groundwater containing VC has not been performed extensively. Approximately 75 percent removal of VC was observed during a pilot test

ERM

IRP SITE 2
ALTERNATIVE 5
ENHANCED BIOREMEDIATION WITH MONITORED NATURAL ATTENTUATION
PLAN VIEW OF TREATMENT SYSTEM LAYOUT

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-4

G:\\6049\71
60497153.dwg, 07/06/01

performed using ORC® at IRP Site 2. It is expected that VC and cis-1,2-DCE will degrade following the creation of enhanced aerobic conditions, but it is uncertain whether the treatment will reduce concentrations to those below RAOs.

This alternative is expected to take longer to begin significant reduction of VOCs than other alternatives, because native microbes must acclimate to the enhanced environment following injection.

Compliance with ARARs. The ability of this alternative to reach ARARs through treatment is uncertain. The use of a hydrogen releasing material is expected to effectively reduce concentrations of TCE to below ARARs. The effectiveness of enhanced aerobic bioremediation at reducing VC to the very low concentrations specified by chemical-specific ARARs is uncertain. Any injection activities must be coordinated through the Oregon UIC program described in Section 4.1.3.6. Compliance with this program is expected to be achievable through registration, monitoring, and reporting.

Long-Term Effectiveness and Permanence. The residual risk posed by Shallow Zone and Deep Zone groundwater at IRP Site 2 would be reduced by this alternative because the contaminants associated with the risks are degraded to harmless byproducts. Although it is uncertain if this alternative will reduce VC to below the significant adverse-effect level at the site, the reduction resulting from treatment should be sufficient to prevent off-site migration, thereby likely meeting the first RAO. Groundwater monitoring would be required for an extended period to verify attainment of this RAO.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV through Treatment. Enhancing bioremediation in IRP Site 2 groundwater will reduce the toxicity, mobility, and volume of VOCs. This is performed through irreversible biological destruction, rather than transfer of contaminants from one media to another. The amount of VOCs that will be degraded by enhanced bioremediation at this site is unknown. A significant reduction of VOC concentration is expected, though, which will result in significant reduction of toxicity.

Mobility and volume of contaminated groundwater are also expected to decrease.

Short-Term Effectiveness. This alternative is expected to take a short period to begin effective removal, thus delaying the reduction of risk. Natural biological activity at IRP Site 2 has been shown to be stagnant, and will require acclimation following injection of an enhancing product.

Groundwater containing unacceptable VOC concentrations has not migrated off Base, and is not expected to reach Base boundaries in the immediate future. Also, the institutional and engineering controls used as part of this alternative will prevent exposure to VOCs at the site. These factors limit the added risks related to the delayed effectiveness of this alternative.

Implementability. No issues have been identified for the installation of this alternative. The materials will be injected using a direct-push method.

The treatment of groundwater with oxygen releasing material relies on the flow of groundwater past the injection locations more than the flow of injected material into surrounding groundwater. The shallow gradient of groundwater at IRP Site 2 will limit the rate of transfer of oxygen created by injected material to the surrounding groundwater.

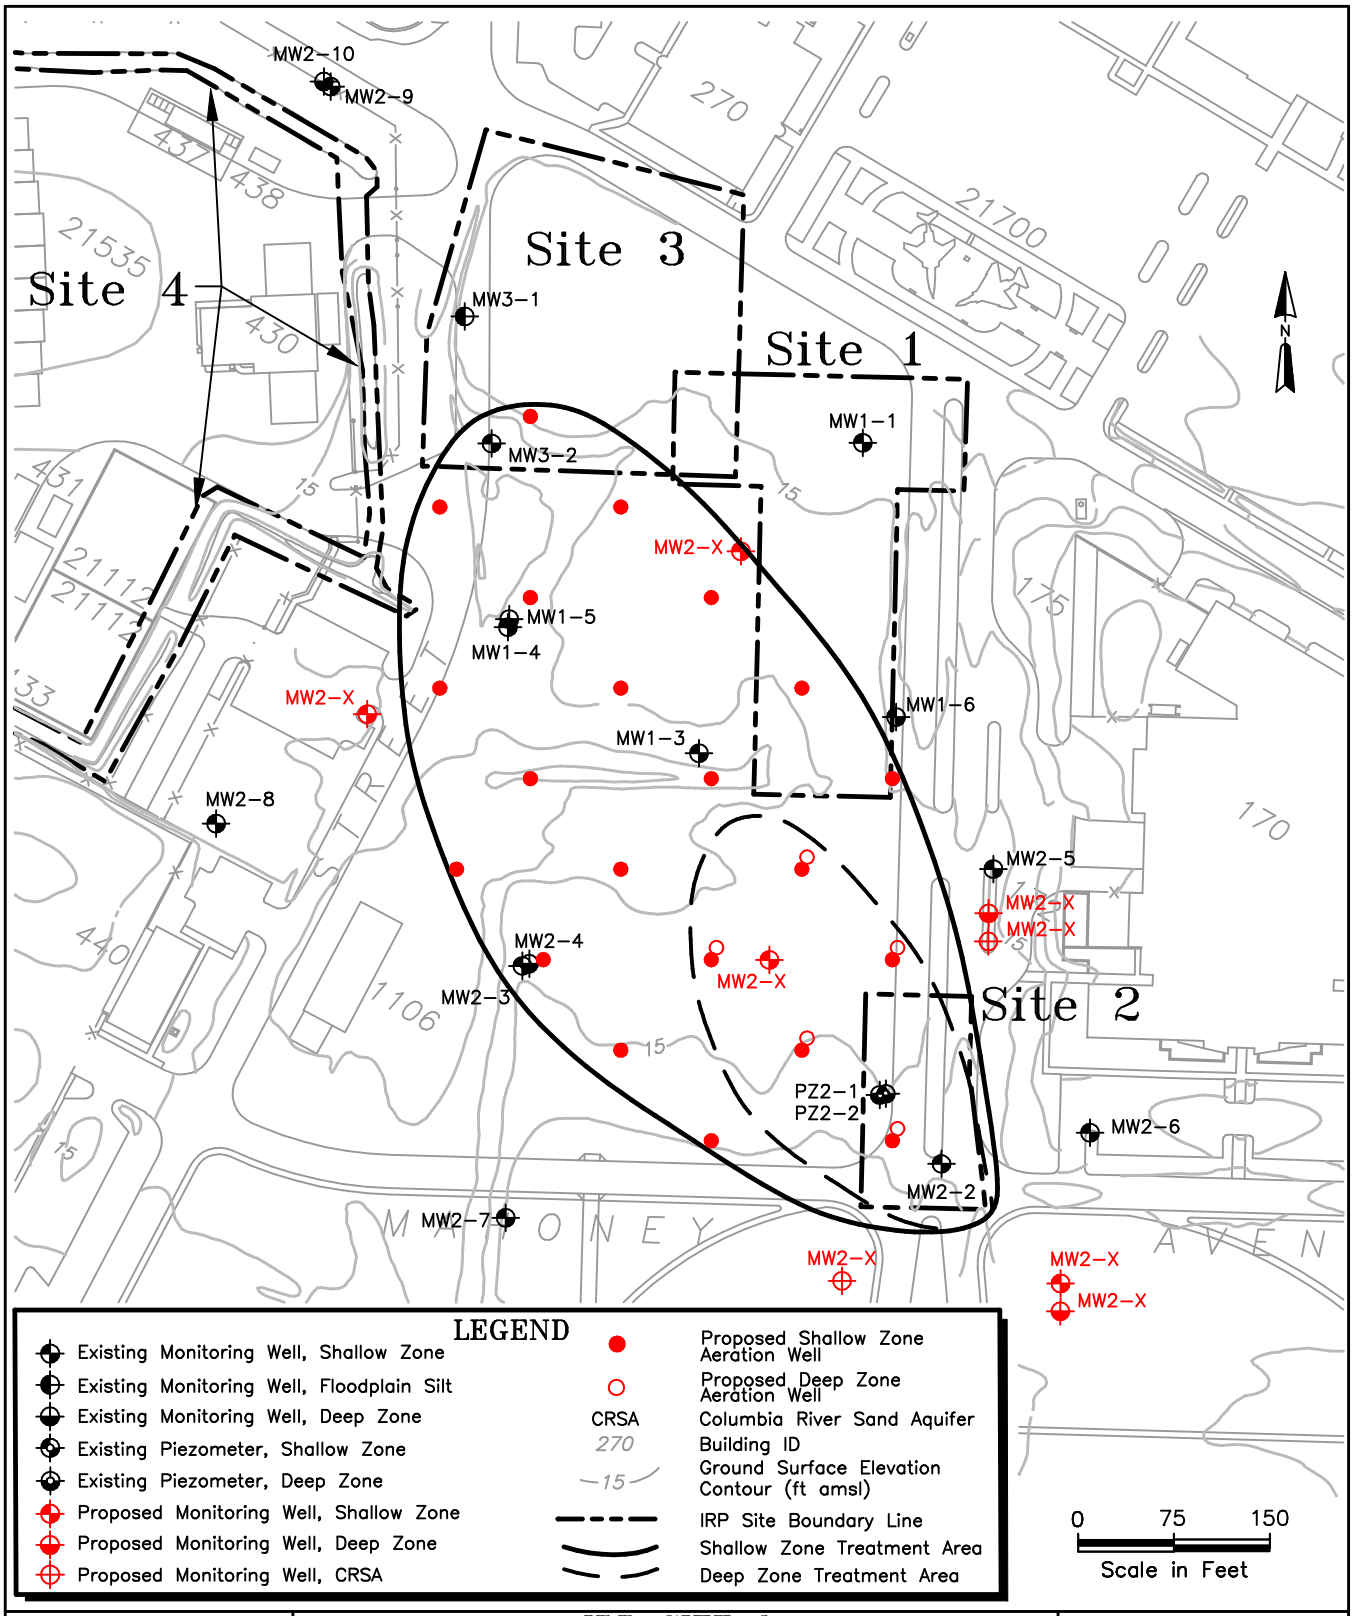
The injection of any material will require coordination with the ODEQ UIC program. This will create scheduling delays due to ODEQ review and public participation requirements.

Cost. Capital and O&M costs associated with Alternative 5 are summarized in Table B-2 and detailed in Table B-6. Direct and indirect capital costs for this alternative are estimated to be $1,806,850, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 2 years is estimated to be $220,000, which assumes quarterly groundwater sampling. The O&M cost for the following 5 years is estimated to be $27,500 per year, which assumes annual groundwater sampling. The net present value of 7 years of O&M costs is $331,300, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 5, including a 30 percent contingency, is $2,780,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Alternative 5 is one of the least expensive of all the alternatives. However, this alternative is not expected to meet the RAOs for the site in a reasonable time period, and is therefore not protective. As a result, this alternative has a mid-range degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat most VOCs at IRP Site 2 to below respective, significant adverse-effect levels within a reasonable timeframe. It is unknown if VC is capable of being treated to its significant adverse effect level of 2 µg/l (ODEQ 1998c) within a reasonable timeframe by this method.

State Acceptance. The use of enhanced bioremediation to treat groundwater at the Base has been accepted by ODEQ for relatively small-scale implementation and is expected to be acceptable for full-scale application.



Community Acceptance. The use of enhanced bioremediation is not expected to have community resistance. However, since this technology is less established for treatment of chlorinated hydrocarbons, the community may be skeptical that it would effectively achieve cleanup goals.

5.2.1.6 IRP Site 2 - Alternative 6: In-Well Aeration with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 6 at IRP Site 2 with respect to the criteria described in Section 5.1. Figure 5-5 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative would reduce the risk posed by IRP Site 2 by reducing the concentration of VOCs in Shallow Zone and Deep Zone groundwater, and the potential for contaminated groundwater to migrate to off-site receptors. The risks associated with exposure to these compounds would be reduced to an acceptable level, based on the current and future land use.

Compliance with ARARs. This alternative is expected to reduce VOCs in IRP Site 2 groundwater to below chemical-specific ARARs. Groundwater within the zone of active treatment by in-well aeration is expected to be treated to concentrations below ARARs within a reasonable time-frame. MNA is expected to degrade VOCs in downgradient groundwater outside of the radius of influence of the in-well aeration system to below ARARs, although at a slower rate than within the active treatment zone.

PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-5

G:\\6049\71
60497154.dwg, 07/06/01

Long-Term Effectiveness and Permanence. The residual risk posed by IRP Site 2 would be reduced by this alternative because the risk posed by the VOCs in Shallow Zone and Deep Zone groundwater would be significantly reduced. Groundwater monitoring will be required beyond the operation of the in-well aeration system to verify attainment of the clean-up goals.

The contaminants in the downgradient areas of the site treated by MNA are expected to be destroyed within a reasonable timeframe, due to enhanced aerobic conditions from upgradient aeration. However, if long-term monitoring indicates that VOCs in this area are not degrading at an acceptable rate, expansion of the aeration system will be considered to actively treat this area.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV Through Treatment. Unlike other treatment technologies discussed in this FS, this technology is based on the transfer of contaminant from one media to another, rather than destruction. Transferring the VOCs from the groundwater to the activated carbon reduces the mobility and volume of the contaminants. The reduction of toxicity of the contaminants would depend on the final disposition of the spent carbon. If the spent carbon is to be disposed of at a landfill, the toxicity is not reduced. This process is irreversible if the activated carbon is handled properly.

Short-Term Effectiveness. It is difficult to estimate with accuracy the time required to achieve the remediation goal. Based on similar scenarios, the in-well aeration system should reduce VOC concentrations in groundwater to below treatment goals within 3 years. The area to be treated by MNA will not experience reductions at the same rate as the in-well aeration area. However, the risks associated with this area are lower.

Implementability. Implementability issues identified for the implementation of this alternative include installation of sub-grade piping across base roads (if necessary), avoidance of underground utilities, and connection to base utilities.

This technology has been shown to effectively remove VOCs from groundwater in locations with adequate subsurface flow characteristics. However, it is still considered an innovative technology, and has not been tested as extensively as some other technologies.

Cost. Capital and O&M costs associated with Alternative 6 are summarized in Table B-2 and detailed in Table B-7. Direct and indirect capital costs for this alternative are estimated to be $1,971,250, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 3 years is estimated to be $777,900, which assumes quarterly groundwater sampling and 3 years of treatment system operation. The O&M cost for the following 5 years is estimated to be $27,500 per year, which assumes annual groundwater sampling. The net present value of 8 years of O&M costs is $891,000, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 6, including a 30 percent contingency, is $3,721,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to -30 percent.

Alternative 6 is expected to meet the RAOs for the site within a reasonable time period, and is therefore protective. However, this alternative is the most expensive alternative, and therefore has a mid-range degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat the VOCs in Shallow Zone and Deep Zone groundwater at IRP Site 2 to below significant adverse effect levels within a reasonable timeframe.

State Acceptance. The use of in-well aeration to treat groundwater at the Base would be expected to be acceptable by ODEQ for full-scale implementation. There are no significant water quality issues related to implementation of this technology, which is a major issue with ODEQ.

Community Acceptance. The use of in-well aeration to treat groundwater at the Base would be expected to be acceptable by community residents.

5.2.2 Comparative Analysis of Alternatives – IRP Site 2

The above-detailed evaluation consisted of an individual analysis of each of the six RA alternatives for IRP Site 2 with respect to: protectiveness, compliance with ARARs, long-term effectiveness and permanence, reduction of TMV through treatment, short-term effectiveness,

implementability, cost, and treatment of hot spots. Below, the alternatives are compared to each other, and rated based on how well each satisfies the evaluation criteria. Because all of the action alternatives involve the completion of a set of common tasks, the following comparative analysis will focus only on those actions that are in addition to the common tasks for a specific alternative.

5.2.2.1 IRP Site 2 - Overall Protection of Human Health and the Environment

Chemically impacted groundwater at IRP Site 2 does not pose immediate risk to human health and the environment because the impacted groundwater is not currently used. Therefore, all of the alternatives are equally protective in the immediate timeframe. However, since the exposure pathway used for this FS considers migration of impacted groundwater to other water bodies, such as deeper aquifers or surface water, the most protective alternative would be that which would most reliably, completely, and quickly remove those chemicals impacting groundwater at IRP Site 2.

Alternatives 1 (No Action) and 2 (MNA) are not expected to reliably, completely, or quickly remove the chlorinated VOCs impacting groundwater at IRP Site 2.

The reliability of Alternative 6 (In-Well Aeration with MNA) is uncertain. A technology similar to Alternative 6 has been shown to remove VOCs from groundwater extracted from the Shallow Zone at IRP Site 2. However, the recirculation-well form of this technology proposed for this FS has not been tested at the Base.

Alternative 5 (Enhanced Bioremediation with MNA) is expected to reliably and quickly remove risks associated with chlorinated VOCs impacting groundwater at IRP Site 2. It was proven during the IRAC treatability test that the site contaminants can be reduced by an oxygen releasing material. However, Alternative 5 is not expected to reduce VOC concentrations enough to meet the RAOs. It is expected that the effectiveness of a bioremediation enhancing material will diminish as the amount of VOCs and other organic material decreases.

Alternative 4 is expected to reliably and quickly reduce concentrations of VOCs. However, since this technology relies on a recirculation principle similar to that in Alternative 6, its reliability is uncertain.

The alternative that is the most protective of human health and the environment is Alternative 3. Like alternatives based on other

technologies, this alternative has been proven to quickly destroy chlorinated VOCs in groundwater at the Base. This alternative is much more reliable and thorough than others because potassium permanganate provides residual treatment capacity and the effectiveness of this technology is more easily monitored. Incomplete removal under this alternative is easily remedied by repeated injections of potassium permanganate.

5.2.2.2 IRP Site 2 - Compliance with ARARs

The ARAR that governs this FS is the federal MCL for each of the chlorinated VOCs impacting groundwater. The alternatives that are not expected to comply with this ARAR include Alternatives 1, 2, and 5, as these options are not expected to reduce the concentration of VC to below the MCL of 2 µg/l for this compound.

Alternatives 4 and 6 do have the potential to reduce concentrations of VOCs to below the respective ARARs. However, as described above, the ability of these technologies to meet this goal across a plume of groundwater is uncertain.

Alternative 3 will most reliably treat VOCs in groundwater at IRP Site 2 to below ARARs. Because of the complete destruction of VOCs that occurs upon contact with potassium permanganate solution, and the simplicity of delivery, this alternative can be tailored in the field to provide complete destruction of VOCs impacting groundwater.

5.2.2.3 IRP Site 2 - Long-Term Effectiveness and Permanence

Alternatives 1 and 2 do not provide long-term effectiveness. These alternatives are not expected to reduce concentrations of VOCs in groundwater at IRP Site 2 to below the respective significant adverse effect levels.

Alternatives 3, 4, and 5 will provide equal long-term effectiveness, provided that these options uniformly meet RAOs as well. These alternatives utilize technologies that provide in situ destruction of contaminants. These technologies are not reversible and do not pose additional risks after meeting treatment goals.

Alternative 6 will provide similar long-term effectiveness to that of Alternatives 3, 4, and 5. However, rather than destroying the contaminants in situ, this alternative uses a technology that strips VOCs

from groundwater, and moves them above ground through sparged air. The VOCs are then destroyed. This technology is also non-reversible and poses no additional risks after meeting treatment goals.

Alternative 3 is the most effective alternative in the long term because of the greater residual ability of potassium permanganate to destroy VOCs.

5.2.2.4 IRP Site 2 - Reduction of Toxicity, Mobility, or Volume through Treatment

Alternatives 1 and 2 will not significantly reduce TMV of groundwater impacted by VOCs at IRP Site 2. Some reduction of toxicity may occur through reduction of VOC concentration at localized areas; however, the mobility and volume will remain unchanged, or may possibly increase.

Alternatives 3, 4, and 6 are expected to effectively reduce the toxicity, mobility, and/or volume of VOC-impacted groundwater at IRP Site 2. Alternative 3 is expected to provide the greatest reduction for all three.

Alternative 5 is expected to significantly reduce the toxicity of groundwater impacted by VOCs. However, since this technology is not expected to provide effective treatment at lower concentrations, the reduction of the volume of impacted groundwater may not be as significant as that of Alternatives 3, 4, and 6.

5.2.2.5 IRP Site 2 - Short-Term Effectiveness

The short-term effectiveness of Alternatives 1 and 2 is unacceptably low, based on the time required to reduce VOC concentrations in groundwater at IRP Site 2. VOCs could possibly migrate off-site or down to the CRSA within the time required to reach cleanup goals under these alternatives.

Alternatives 3, 4, 5, and 6 all provide sufficient short-term effectiveness. These alternatives will significantly reduce VOC concentrations in groundwater in a relatively brief time. Alternatives 3 and 4 pose threats to workers in the form of exposure to the oxidizers potassium permanganate and ozone. These threats can be controlled by the use of health and safety measures. The materials used in Alternative 5 exhibits a slight inhalation danger to workers implementing this alternative. No threats to workers are expected during implementation of Alternative 6 beyond the typical mechanical hazards potentially associated with well drilling and machinery installation.

5.2.2.6 IRP Site 2 - Implementability

Alternatives 1 and 2 are the easiest alternatives to implement as the former requires no action and the latter requires only installation of additional monitoring wells and periodic monitoring of VOCs and natural attenuation parameters. However, the reliability of these alternatives is questionable, and it is expected that these alternatives would require future replacement.

The next easiest alternatives to implement are Alternatives 3 and 5. These alternatives involve the direct-push injection of a treatment material and progress monitoring. Alternative 3 is expected to reduce VOCs more fully in IRP Site 2 groundwater. Alternative 5 may require replacement if it should fail to provide complete reduction.

The implementation of Alternatives 4 and 6 involve the construction of numerous, complex sparge wells, as well as a system of piping, compressors, and controls. These systems would require periodic monitoring, trouble shooting, and maintenance.

5.2.2.7 IRP Site 2 - Cost

Alternative 1 and 2 are the least expensive alternatives; however, these alternatives fail to satisfy the protectiveness criterion because they are not expected to meet the site RAOs within a reasonable time period. These alternatives are therefore not cost reasonable. Alternative 5 is also not expected to meet the RAOs within a reasonable time period, although it is one of the least expensive of the alternatives that employ active remedial measures. As a result, Alternative 5 is not the most cost reasonable option. Alternatives 4 and 6 are expected to meet the site RAOs within a reasonable time period, although, these are the two most expensive alternatives. Alternative 3 meets the same level of protectiveness as Alternatives 4 and 6, but is less expensive. Therefore, Alternative 3 is the most cost reasonable alternative.

5.2.2.8 IRP Site 2 - Treatment of Hot Spots

Alternatives 1 and 2 are not expected to effectively treat hot spots of contamination in groundwater at IRP Site 2. The implementation of either of these alternatives could potentially allow the extent of these hot spots to increase.

All of the remaining alternatives would likely reduce the size of the hot spots at IRP Site 2 through treatment. It is uncertain whether Alternative 5 would be effective at treating VOCs, particularly VC, to below the significant adverse-effect level.

Alternatives 3, 4, and 6 are potentially capable of treating VOCs to below the significant adverse-effect levels; however, the expected reliability of Alternative 3 is greater than the others.

5.2.2.9 IRP Site 2 – State Acceptance

Alternatives 1 and 2 are not expected to effectively treat hot spots of contamination in groundwater at IRP Site 2 and therefore are not expected to be acceptable to ODEQ. All of the remaining alternatives would likely reduce the size of the hot spots at IRP Site 2 through treatment as required by ODEQ. However, the use of potassium permanganate injection would be scrutinized by ODEQ the most due to the injection of an oxidizing fluid into the groundwater.

5.2.2.10 IRP Site 2 – Community Acceptance

Alternatives 1 and 2 are not expected to be acceptable to the community because they are not expected to treat hot spots of contamination in groundwater at IRP Site 2 within a reasonable timeframe.

All of the remaining alternatives would likely reduce the size of the hot spots at IRP Site 2 through treatment and should generally be acceptable to community residents. However, for Alternative 3 using potassium permanganate injection it will be important to implement a monitoring program that will sufficiently allow the public to review water quality data.

5.2.3 IRP Site 2 - Preferred Alternative

Alternative 3 is the preferred alternative because it best satisfies the protectiveness criteria and the remedy-selection balancing factors. Alternative 3 involves direct-push injection of potassium permanganate solution through the vertical extent of both the Shallow Zone and Deep Zone, combined with MNA. This alternative also includes the implementation of the common tasks described in Section 4.5.2. By implementation of Alternative 3, the following achievements are expected:

- Human health and the environment within the locality of facility would be protected over the long term.

- The residual risk associated with VOCs in groundwater remaining after completion of this alternative would be acceptable, as described in Section 6.2.

- Base workers would be protected from exposure to VOCs in groundwater through the use of institutional and engineering controls.

- Compared to the other alternatives, greater cost savings would be realized by utilizing permanganate injection to reduce VOC concentrations in IRP Site 2 groundwater.

The IRAC program described previously in Sections 2.8.2 and 3.2.4 will accomplish some of the components of the preferred alternative for IRP Site 2. The full-scale demonstration that is the second phase of the IRAC program involves the injection of potassium permanganate into Shallow Zone groundwater using the same direct-push injection technique described in this FS. The purpose of the second phase of the IRAC program is to test the effectiveness of the preferred technology from the first phase as it is implemented in a full-scale manner, while serving to destroy a large amount of VOC mass.

The second phase of the IRAC will involve a series of direct-push potassium permanganate injections performed in the southeast area of the VOC plume at IRP Site 2. This area has the highest VOC concentrations in Shallow Zone groundwater at the site.

5.3 IRP Site 9

5.3.1 IRP Site 9 - Individual Analysis of Alternatives

The following presents an evaluation of the RA alternatives for IRP Site 9 against the evaluation criteria. The remedial alternatives evaluated for IRP Site 9 include:

- Alternative 1: No Action

- Alternative 2: MNA

- Alternative 3: In Situ Oxidation – Sodium Persulfate Injection with MNA

- Alternative 4: In Situ Oxidation – Ozone Sparging with MNA
- Alternative 5: Enhanced Bioremediation with MNA
- Alternative 6: In-Well Aeration with MNA

5.3.1.1 IRP Site 9 - Alternative 1: No Action

The following is an evaluation of the application of Alternative 1 at IRP Site 9 with respect to the criteria described in Section 5.1.

Overall Protection of Human Health and Environment. The No Action Alternative would not be protective of human health and the environment in the short term because the risks associated with Shallow Zone groundwater are not immediately reduced, either by treatment or by implementing restrictions that would prevent exposure site groundwater, such as institutional controls. Because contaminated Shallow Zone groundwater has the potential to migrate off-site, the No Action Alternative would not provide long-term protection of human health and the environment.

Compliance with ARARs. The No Action Alternative does not meet chemical-specific ARARs because benzene in Shallow Zone groundwater currently exceeds ARARs. Natural processes may not degrade benzene in IRP Site 9 Shallow Zone groundwater prior to migration off-site, and this alternative provides no mechanism for monitoring potential migration.

Long-Term Effectiveness and Permanence. The No Action Alternative would not provide long-term effectiveness and permanence. Remaining untreated benzene in Shallow Zone groundwater would pose too great a residual risk to human and environmental receptors.

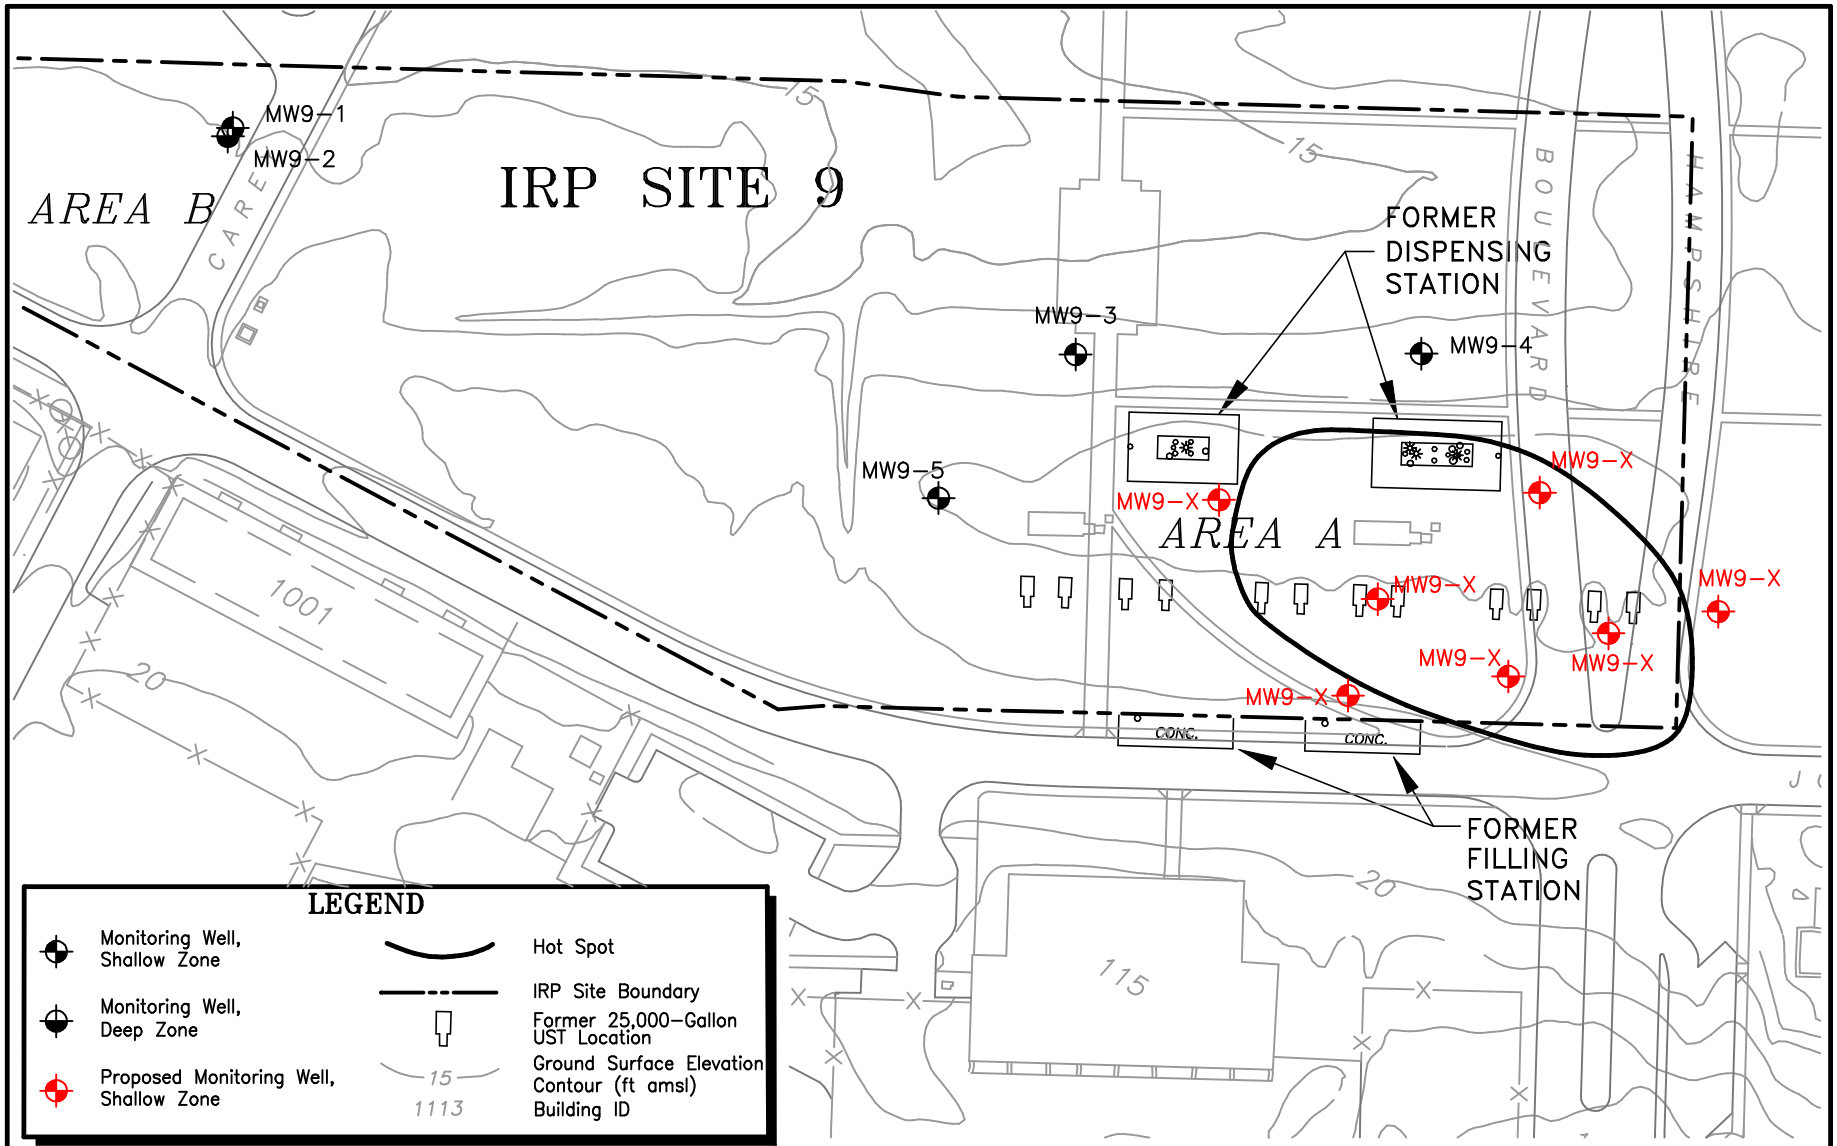
Reduction of TMV Through Treatment. The No Action Alternative does not include treatment to reduce TMV. As a result, it is possible that benzene will migrate laterally off-site, as well as vertically to the underlying Deep Zone. Biodegradation of benzene in Shallow Zone groundwater may continue to occur as observed in the past, but without active monitoring it is impossible to ascertain if the degradation rate is rapid enough to prevent migration. If migration of the plume occurs more rapidly than degradation, the volume of hazardous material could actually increase.

Short-Term Effectiveness. The No Action Alternative would present short-term, human health risks associated with benzene in groundwater. However, these risks are no greater than the existing risks at IRP Site 9.

Implementability. The No Action Alternative would not incur implementation obstacles, and there are no associated O&M requirements.

Cost. No costs would be associated with implementing the No Action Alternative. However, because this alternative is ineffective at meeting the RAOs for the site, it would not be protective and therefore a low degree of cost reasonableness is associated with this alternative.

Treatment of Hot Spots. The No Action Alternative does not meet Oregon's requirement that hot spots in water be treated to below the significant adverse-effect level.



State Acceptance. The No Action Alternative would not be acceptable to ODEQ. Oregon requires that hot spots such as that present in groundwater at IRP Site 9 be treated to below the significant adverse-effect level.

Community Acceptance. The No Action Alternative is not expected to be acceptable to the community. The community is active at the Base in the form of a Restoration Advisory Board (RAB), and would not be accepting of leaving an area of groundwater impacted at the level of IRP Site 9 untreated.

5.3.1.2 IRP Site 9 - Alternative 2 : Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 2 at IRP Site 9 with respect to the criteria described in Section 5.1. Figure 5-6 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. The MNA Alternative would be protective of human health and the environment in the short term. Near-future exposure to groundwater with unacceptable risk is prevented through the implementation of institutional and engineering controls at the Base. Groundwater with benzene concentrations above unacceptable risk levels has not migrated to any off-site receptors, and is not expected to in the near future. However, there is long-term risk associated with off-site migration of groundwater containing benzene. During the Natural Attenuation Evaluation conducted as part of the RI (ERM 2001a), it was concluded that natural biodegradation at IRP Site 9 has become stagnant. Because of this, it is

IRP SITE 9

ALTERNATIVE 2
MONITORED NATURAL ATTENTUATION
LOCATION OF MONITORING WELLS

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-6

possible that Shallow Zone groundwater containing benzene levels above the RAOs has the potential to migrate off-site. The MNA Alternative, therefore, would not provide long-term protection of human health and the environment.

Compliance with ARARs. The MNA Alternative does not meet chemical-specific ARARs because benzene in Shallow Zone groundwater currently exceeds ARARs, and is not expected to naturally degrade to acceptable levels within a reasonable timeframe, as compared to other methods.

Long-Term Effectiveness and Permanence. The MNA Alternative may provide long-term effectiveness and permanence due to eventual natural degradation of benzene below RAOs. However, this is unlikely to occur within a reasonable time period. It is uncertain if this alternative will treat groundwater to appropriate levels prior to migrating off-site, thereby violating the first RAO, and creating the potential need to replace this remedy.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV Through Treatment. The MNA Alternative may reduce the TMV of benzene at IRP Site 9 as natural degradation occurs. The toxicity of Shallow Zone groundwater may slowly diminish as concentrations decrease, but the mobility will remain unchanged. The volume of contaminated groundwater may actually increase due to potential further downgradient and vertical migration of slowly degrading benzene.

Short-Term Effectiveness. The MNA Alternative would present short-term human health risks associated with benzene in groundwater at IRP Site 9. The short-term risks associated with this alternative are a result of the expected time required to meet treatment objectives, expected to possibly exceed 30 years. Within that period, groundwater containing unacceptable benzene concentrations may migrate off-site, thereby violating the first RAO and presenting risk to off-site receptors.

The institutional and engineering controls implemented under this alternative are expected to prevent unacceptable risk to on-site receptors, including Base workers and workers implementing this RA.

Implementability. The MNA Alternative would not incur implementation obstacles. The additional proposed wells will ensure the ability to monitor the effectiveness of this alternative, and the technologies used for this alternative are readily available and implementable.

Cost. Capital and O&M costs associated with Alternative 2 are summarized in Table B-8, and detailed in Table B-9. Direct and indirect capital costs for this alternative are estimated to be $64,500, and include equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first year is estimated to be $40,400, which assumes quarterly groundwater sampling. The O&M cost for the following 30 years is estimated to be $10,100 per year, which assumes annual groundwater sampling. The net present value of 31 years of O&M costs is $159,700, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 2 is $292,000, including a 30 percent contingency. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Because Alternative 2 is not expected to meet the RAOs for the site within a reasonable time period, this alternative is not considered protective and therefore has a low degree of cost reasonableness.

Treatment of Hot Spots. Although MNA is considered a treatment technology by the State of Oregon, it is not expected to treat the hot spot at IRP Site 9 to concentrations below the significant adverse-effect level in a timely manner. The hot spot, defined by the extent of contaminants above respective, significant adverse-effect levels, could potentially expand due to migration of the source area.

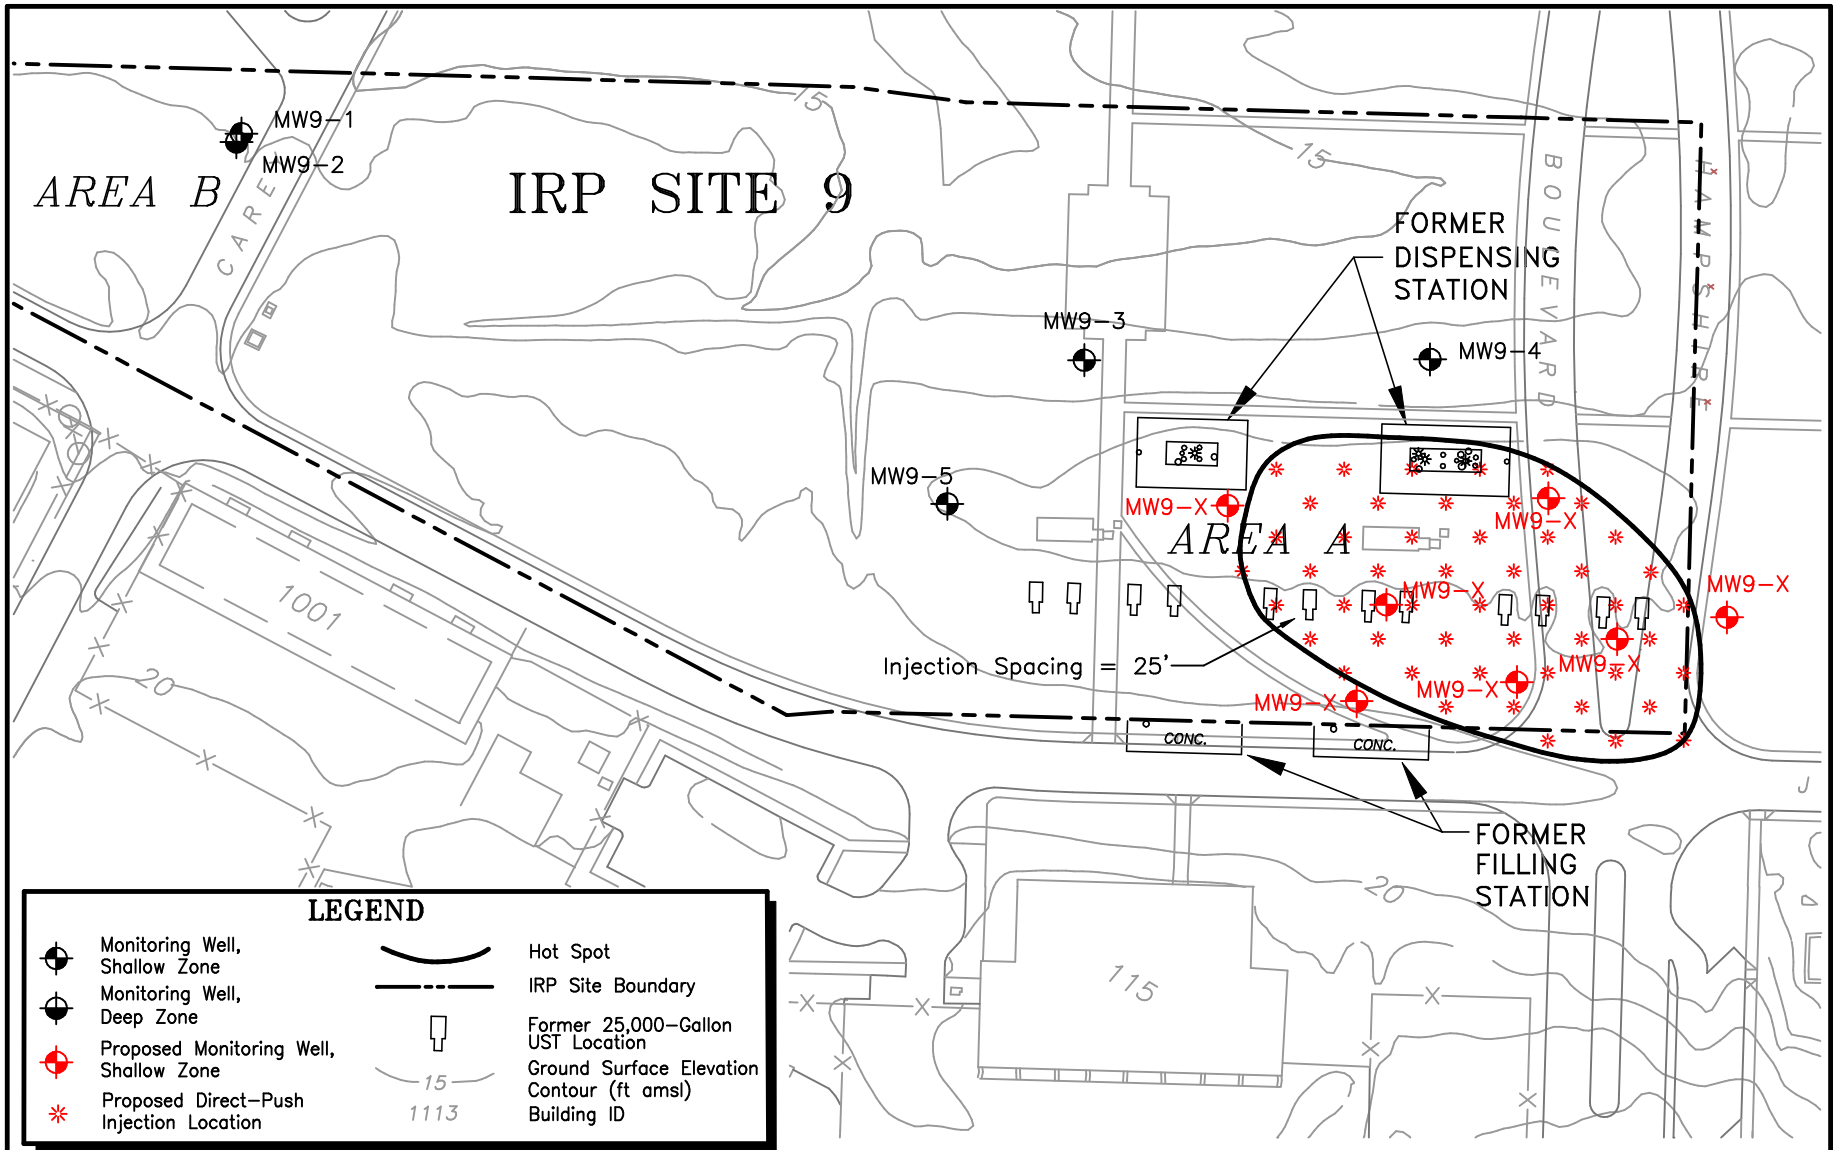
Treatment of Hot Spots. Although MNA is considered a treatment technology by the State of Oregon, the hot spot at IRP Site 2 is not expected to be treated to concentrations below the significant adverse-effect level in a timely manner under this alternative. The hot spot, defined by the extent of contaminants above respective significant adverse-effect levels, could potentially expand due to migration of the source area.

State Acceptance. The Natural Attenuation Alternative would not be expected to be acceptable to ODEQ. Oregon requires that hot spots such as that present in groundwater at IRP Site 9 be treated within a reasonable timeframe and this is not expected to occur using the Natural Attenuation alternative.

Community Acceptance. The Natural Attenuation Alternative is not expected to be acceptable to the community due to the expected duration required to meet treatment goals.

5.3.1.3 IRP Site 9 - Alternative 3: In Situ Oxidation – Sodium Persulfate Injection with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 3 at IRP Site 9 with respect to the criteria described in Section 5.1. Figure 5-7 depicts the layout of the primary components of this alternative.



Overall Protection of Human Health and Environment. This alternative is expected to significantly reduce the benzene concentrations from IRP Site 9 Shallow Zone groundwater, and the associated risks of exposure to these compounds. The level of benzene reduction via sodium persulfate oxidation is uncertain, as this technology has not been tested on Base groundwater.

Compliance with ARARs. This alternative is expected to effectively reduce benzene concentrations in IRP Site 9 Shallow Zone groundwater. Any injection activities must be coordinated through the Oregon UIC program described in Section 4.1.3.6. Compliance with this program is expected to be achievable through registration, monitoring, and reporting.

Long-Term Effectiveness and Permanence. The residual risk posed by IRP Site 9 Shallow Zone groundwater would be reduced by this alternative because the contaminants associated with the risks would be destroyed. After the completion of this alternative, extended groundwater monitoring would be required to verify attainment of the RAOs.

The contaminants in the downgradient areas of the site treated by MNA are expected to be destroyed within a reasonable timeframe, due to enhanced conditions from upgradient persulfate injection.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land-use scenarios. However, care must be taken to ensure that the

IRP SITE 9

ALTERNATIVE 3
IN SITU OXIDATION-SODIUM PERSULFATE INJECTION WITH MONITORED NATURAL ATTENTUATION

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-7

controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV through Treatment. The use of sodium persulfate oxidation and MNA to treat benzene in groundwater will result in reduced TMV of hazardous materials in IRP Site 9 groundwater. This reduction is performed through chemical and biological destruction, rather than transfer of contaminants from one media to another. The treatment process is irreversible and would result in the production of only harmless byproducts.

Short-Term Effectiveness. Workers performing the injection will be in contact with sodium persulfate in solid or dissolved form. Worker exposure would be minimized by the use of appropriate health and safety personal protective equipment.

Adverse effects on groundwater used for drinking or irrigation is not expected. The oxidative effects of the sodium persulfate would diminish with time, as it reacts with organic material in the subsurface.

Risks associated with VOCs in groundwater are quickly reduced due to the rapid treatment resulting from persulfate oxidation. Destruction of VOCs in areas treated by sodium persulfate is expected to be complete within 1 to 2 years.

Implementability. The implementability of this alternative may be inhibited by site geology, as preferential flow paths and areas of low conductivity will determine the flow of the injected sodium persulfate. As such, the injected material may not reach limited regions of an aquifer; however, this can be overcome by reducing the grid spacing for the direct-push injection, and staggering the locations of later injections.

The injection of sodium persulfate will require coordination with the ODEQ UIC program, which may create scheduling delays due to the ODEQ's review and public participation requirements.

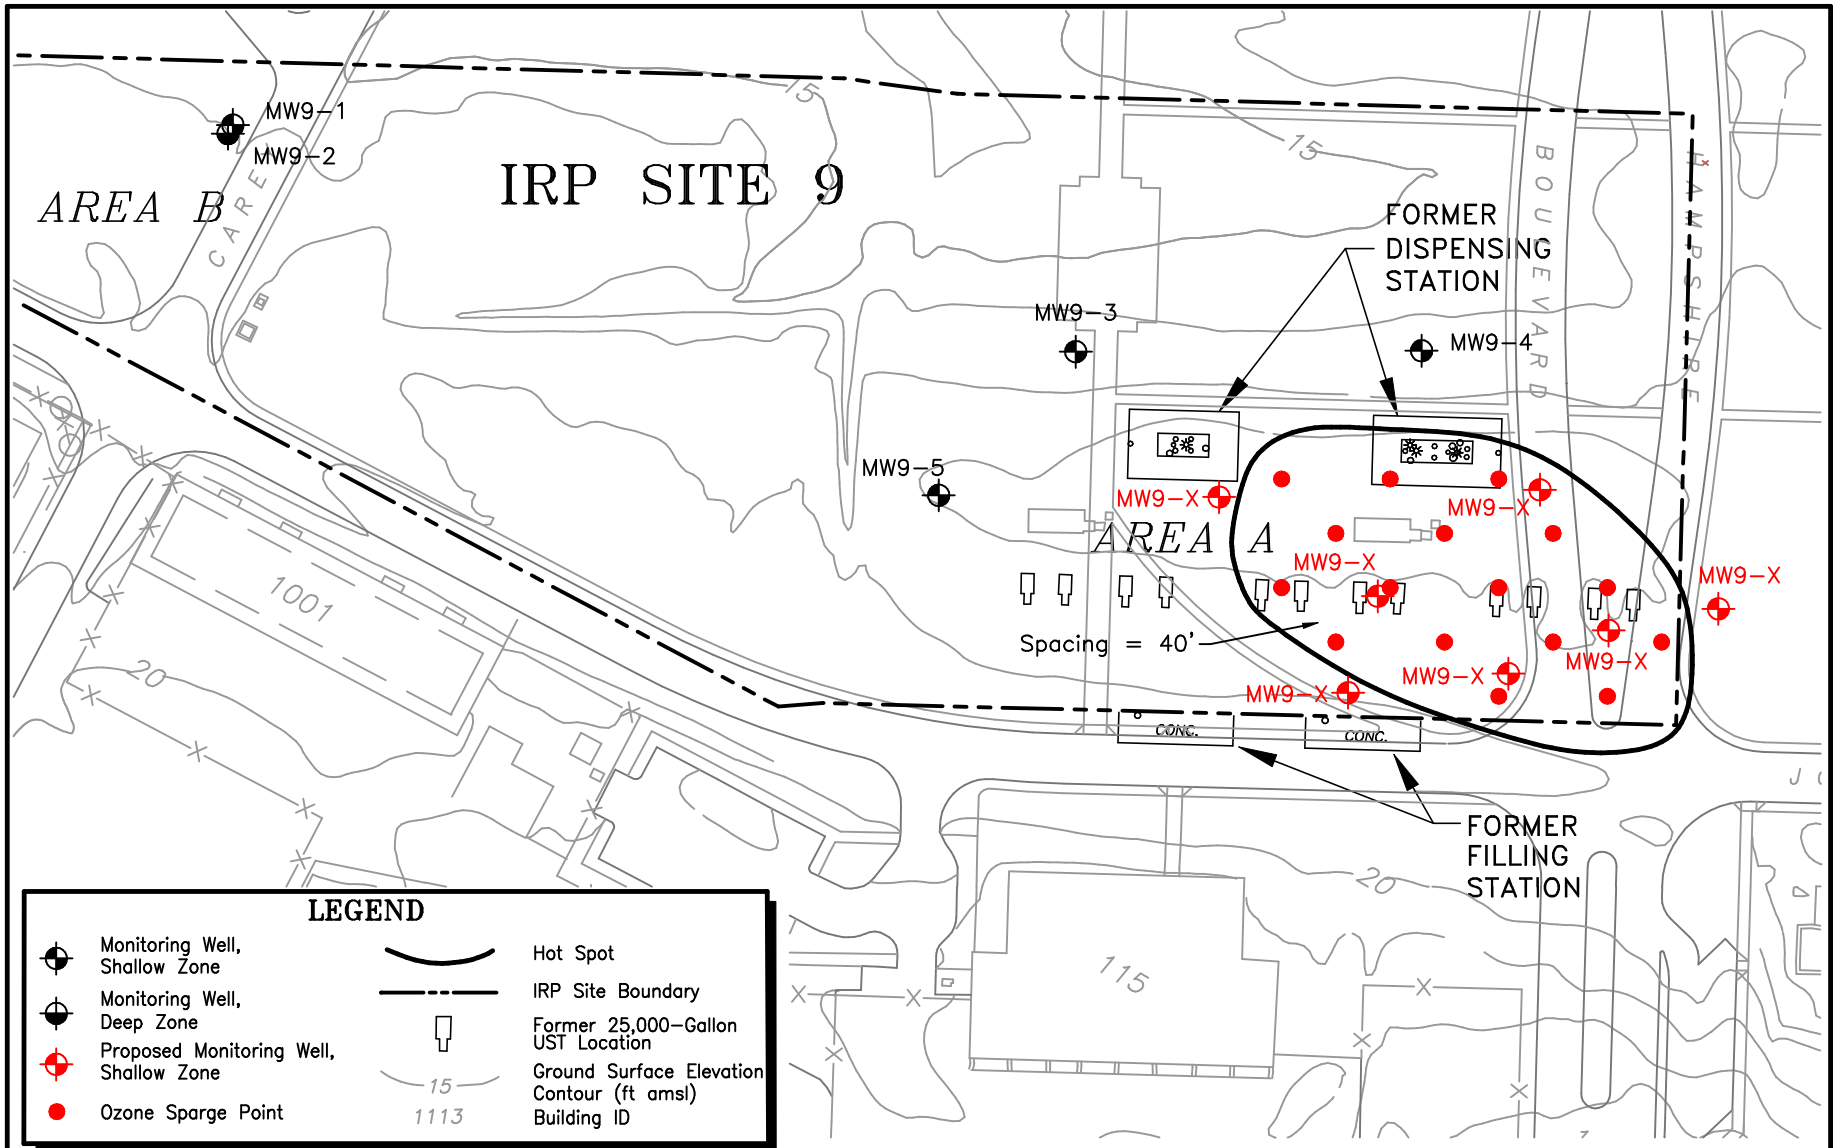
The technical aspects of the actual direct-push injection of sodium persulfate are basic, and should not present constraints.

Cost. Capital and O&M costs associated with Alternative 3 are summarized in Table B-8, and detailed in Table B-10. Direct and indirect capital costs for this alternative are estimated to be $319,000, and include equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for

the first 2 years is estimated to be $80,800, which assumes quarterly groundwater sampling. The O&M cost for the following 5 years is estimated to be $10,100 per year, which assumes annual groundwater sampling. The net present value of 7 years of O&M costs is $121,700, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 3 is $573,000, including a 30 percent contingency. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to a degree of +50 to –30 percent.

Alternative 3 is the least expensive of the alternatives that employ active remedial measures. Additionally, this alternative is expected to meet the RAOs for the site within a reasonable time period and is thus protective. As a result, this alternative has a high degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat the benzene at IRP Site 9 to below significant adverse effect levels within a reasonable timeframe.



State Acceptance. The use of in situ oxidation to treat groundwater at the Base has been accepted by ODEQ for relatively small-scale implementation and is expected to be acceptable for full-scale application. However, ODEQ approval of a large scale use of sodium persulfate injection is likely to be contingent on an appropriate monitoring and reporting plan to ensure compliance with the UIC program.

Community Acceptance. The use of sodium persulfate is expected to have some community resistance since it relies on the injection of a foreign material into the groundwater. An appropriate monitoring and reporting system is an important component of this alternative to allow the public the opportunity to monitor water quality during the remedial action.

5.3.1.4 IRP Site 9 - Alternative 4: In Situ Oxidation – Ozonation with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 4 at IRP Site 9 with respect to the criteria described in Section 5.1. Figure 5-8 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative is expected to effectively remove or significantly reduce the benzene concentrations from IRP Site 9 groundwater. The risks associated with benzene exposure would be reduced to an acceptable level, based on current and future land use.

IRP SITE 9

ALTERNATIVE 4
IN SITU OXIDATION-OZONATION WITH MONITORED NATURAL ATTENTUATION

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-8

Compliance with ARARs. This alternative is expected to effectively reduce benzene concentrations in Shallow Zone groundwater to below the levels set by chemical-specific ARARs. Any injection activities must be coordinated through the Oregon UIC program described in Section 4.1.3.6. Compliance with this program is expected to be achievable through registration, monitoring, and reporting.

Long-Term Effectiveness and Permanence. The residual risk posed by IRP Site 9 Shallow Zone groundwater would be reduced by this alternative because the contaminants associated with the risks are destroyed. Groundwater monitoring would be required for an extended period after the completion of this alternative to verify attainment of the RAOs.

The contaminants in the downgradient areas of the site treated by MNA are expected to be destroyed within a reasonable timeframe, due to enhanced conditions from upgradient ozonation. However, if long-term monitoring indicates that benzene in this area has not degraded at an acceptable rate, expansion of the area of ozonation would be considered.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV Through Treatment. The use of ozonation will reduce the TMV of benzene in IRP Site 9 groundwater via chemical destruction, rather than transfer of contaminants from one media to another. This treatment process is irreversible, and would result in the production of only harmless byproducts.

Short-Term Effectiveness. Ozone is a strong oxidant and care must be taken to prevent worker or Base employee exposure to ozone generated for injection. This would include periodic monitoring of ozone in workspace air, and enclosing and locking the ozone generator and sparge wellheads to prevent tampering.

Adverse effects on groundwater used for drinking or irrigation purposes is not expected. The oxidative effects of ozone are short lived in groundwater.

Risks associated with benzene in groundwater are quickly reduced due to the rapid treatment resulting from ozonation. Destruction of VOCs in

areas treated by ozonation is expected to be complete within approximately 3 years.

Implementability. Implementability issues associated with this alternative include installation of sub-grade piping across Base roads (if necessary), avoidance of underground utilities, and connection to Base utilities. The installation and monitoring of an ozone sparging system would require extensive labor as compared to technologies that simply involve injection and monitoring.

The implementability of this alternative may be inhibited by site geology, as preferential flow paths and areas of low conductivity will determine where sparged air will flow. This can usually be overcome by utilizing a pulsed sparging technique consisting of alternating periods of sparging and rest.

The injection of ozone will require coordination with the ODEQ UIC program, which could create scheduling delays due to ODEQ's review and public participation requirements.

Cost. Capital and O&M costs associated with Alternative 4 are summarized in Table B-8, and detailed in Table B-11. Direct and indirect capital costs for this alternative are estimated to be $570,700, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 3 years is estimated to be $309,900, which assumes quarterly groundwater sampling and 3 years of treatment system operation. The O&M cost for the following 5 years is estimated to be $10,100 per year, which assumes annual groundwater sampling. The net present value of 8 years of O&M costs is $350,800, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 4 is $1,198,000, including a 30 percent contingency. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

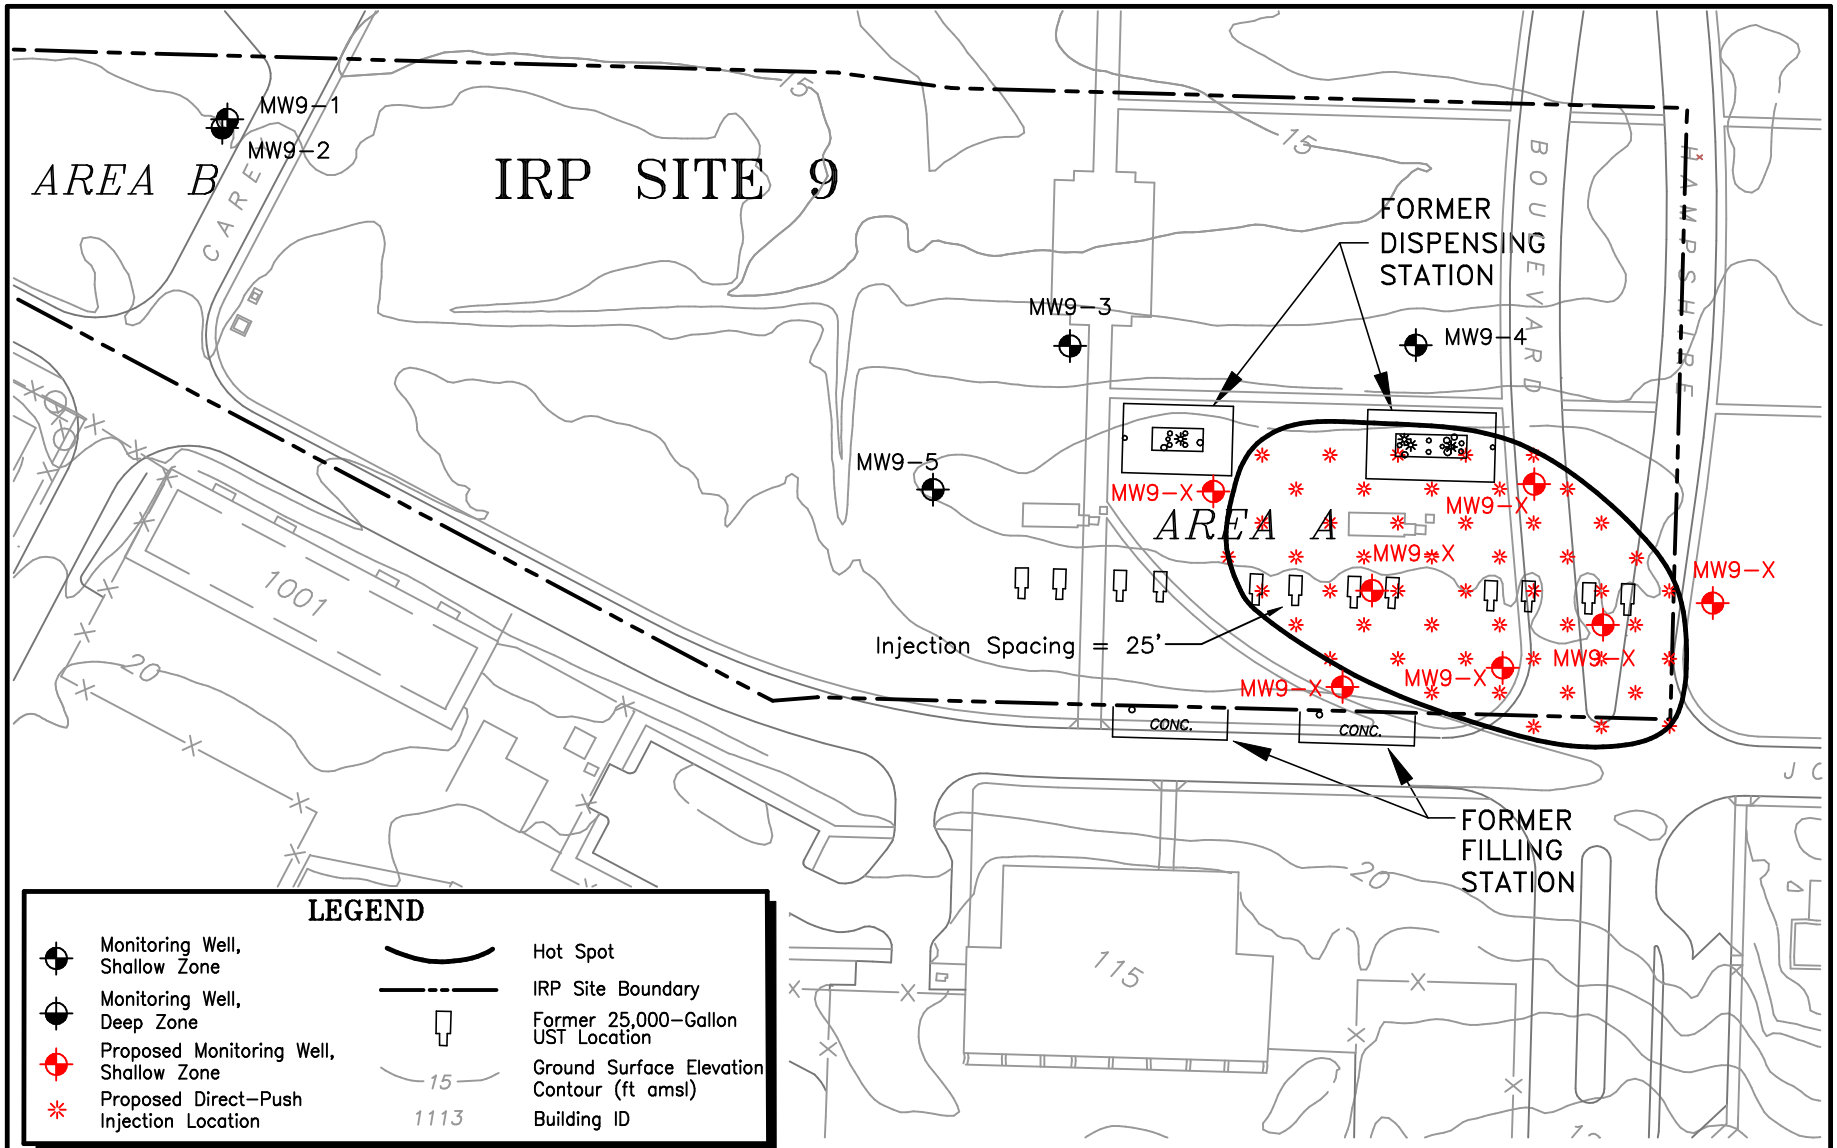
Alternative 4 is expected to meet the RAOs for the site within a reasonable timeframe and is thus protective. However, Alternative 4 is the most expensive alternative, and therefore has a medium degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat the benzene at IRP Site 9 to below significant adverse-effect levels within a reasonable timeframe.

State Acceptance. The use of ozonation to treat groundwater at the Base has been accepted by ODEQ for relatively small-scale implementation and is expected to be acceptable for full-scale application. However, ODEQ approval of larger scale use of an injection technology is likely to be contingent on an appropriate monitoring and reporting plan to ensure compliance with the UIC program.

Community Acceptance. The use of ozonation is expected to have less community resistance than other injection technologies since it relies on the injection of a short-lived gas rather than a liquid. However, an appropriate monitoring and reporting system is still an important component of this alternative to allow the public the opportunity to monitor water quality during the remedial action.

5.3.1.5 IRP Site 9 - Alternative 5: Enhanced Bioremediation with Monitored Natural Attenuation



The following is an evaluation of the application of Alternative 5 at IRP Site 9 with respect to the criteria described in Section 5.1. Figure 5-9 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative is expected to effectively remove benzene from IRP Site 9 Shallow Zone groundwater, and the risks associated with exposure to this contamination. This alternative is expected to take longer than other alternatives because native microbes must acclimate to the enhanced environment following injection.

Compliance with ARARs. This alternative is expected to effectively reduce the concentration of benzene in Shallow Zone groundwater to below the levels set by chemical-specific ARARs. Any injection activities must be coordinated through the Oregon UIC program described in Section 4.1.3.6. Compliance with this program is expected to be achievable through registration, monitoring, and reporting.

Long-Term Effectiveness and Permanence. The residual risk posed by Shallow Zone groundwater at IRP Site 9 would be reduced by this alternative because the contaminants associated with the risks are degraded to harmless byproducts. Groundwater monitoring would be required for an extended period after the completion of this alternative to verify attainment of the RAOs.

The institutional and engineering controls implemented as part of this alternative would likely be reliable in the long term, based on the current

IRP SITE 9

ALTERNATIVE 5
ENHANCED BIOREMEDIATION
WITH MONITORED NATURAL ATTENTUATION

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-9

and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV Through Treatment. Enhancing bioremediation in IRP Site 9 groundwater will reduce the TMV of benzene. This is performed through irreversible biological destruction, rather than transfer of contaminants among media.

Short-Term Effectiveness. This alternative is expected to take a short period to begin effective removal, thus delaying the reduction of risk. Natural biological activity at IRP Site 9 has been shown to be stagnant, and would require acclimation following injection of an enhancing product.

Groundwater containing unacceptable benzene concentrations has not migrated off Base, and is not expected to reach Base boundaries in the very near future. Also, the institutional and engineering controls used as part of this alternative would prevent benzene exposure at the site. These factors limit the added risks related to the delayed effectiveness of this alternative.

Implementability. No issues have been identified for the installation of this alternative. The materials would be injected using a direct-push method.

The treatment of groundwater with oxygen releasing materials relies more heavily on the flow of groundwater past the injection locations, than the flow of injected material into surrounding groundwater. The shallow gradient of groundwater at IRP Site 9 would serve to limit the rate of transfer of oxygen created by the injected material to the surrounding groundwater.

The injection of any oxygen releasing material will require coordination with the ODEQ UIC program. This will create scheduling delays due to ODEQ review and public participation requirements.

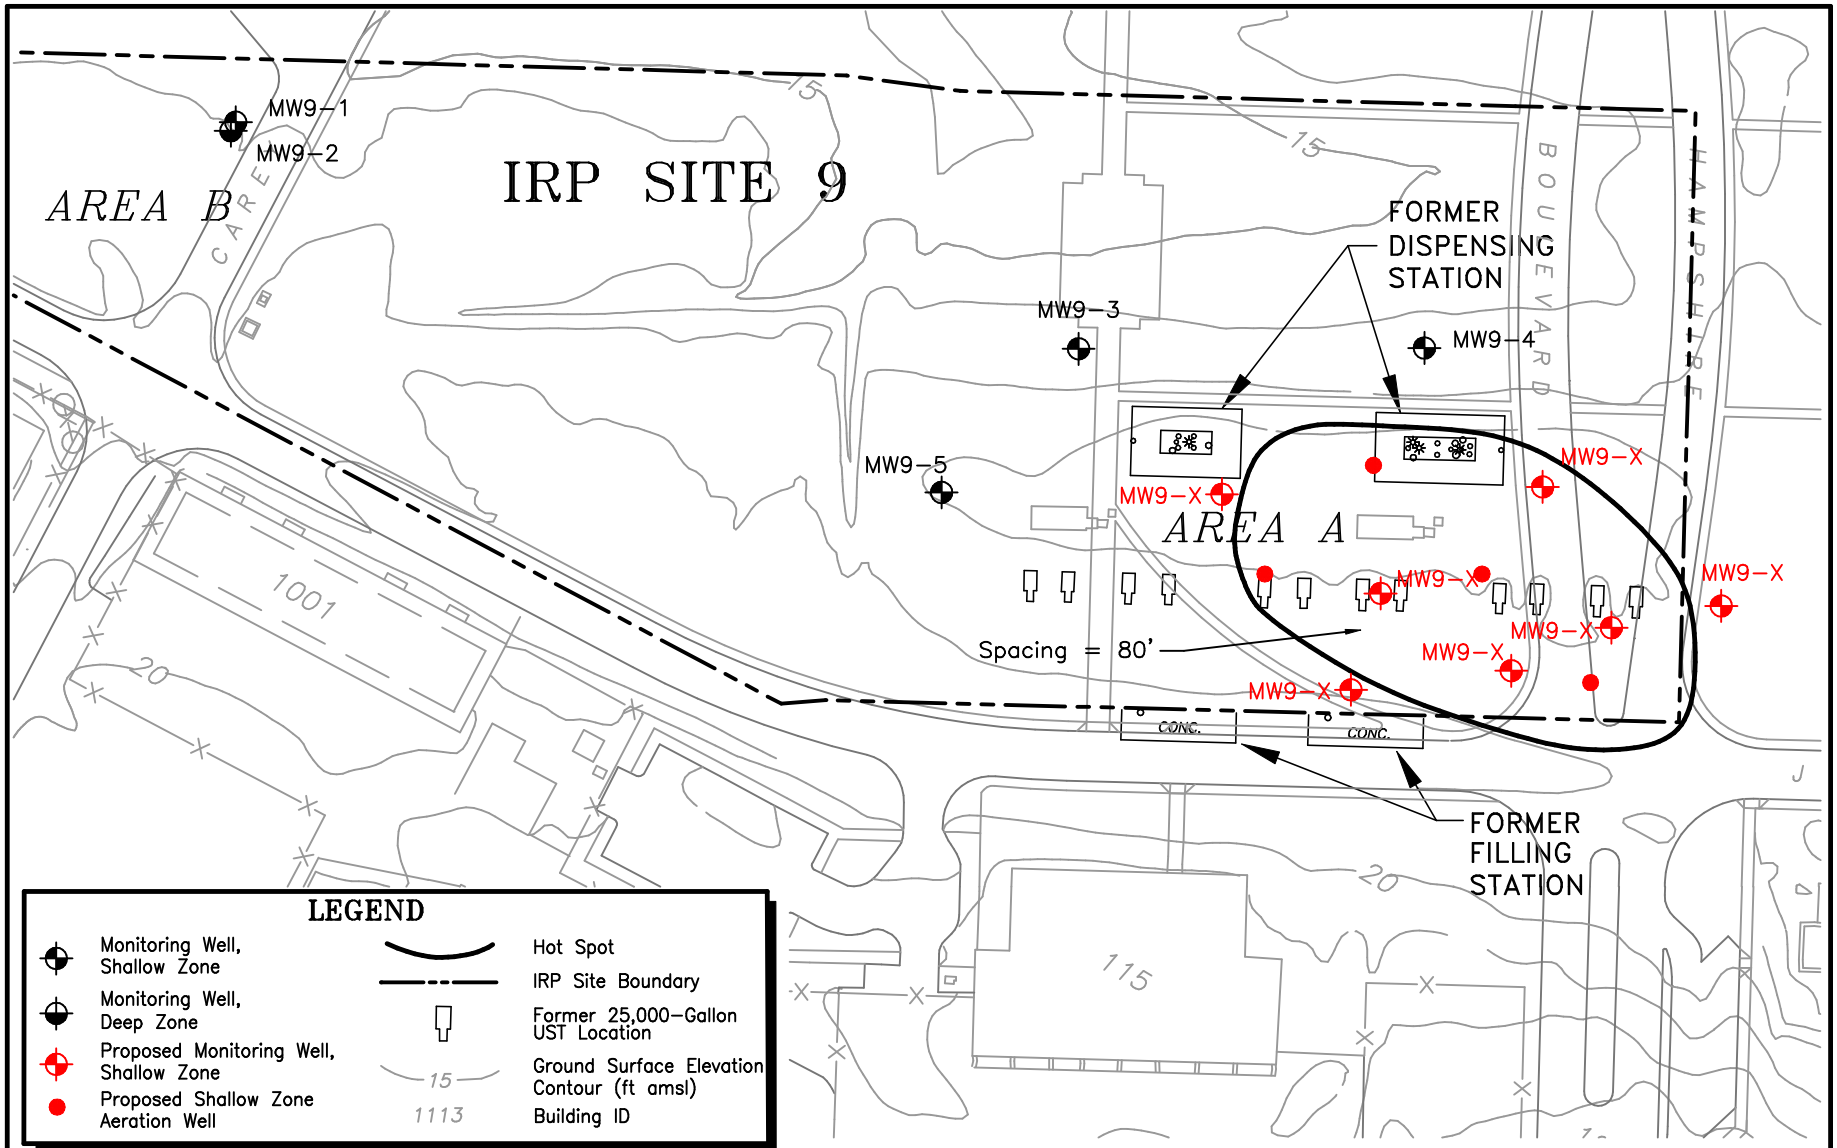
Cost. Capital and O&M costs associated with Alternative 5 are summarized in Table B-8, and detailed in Table B-12. Direct and indirect capital costs for this alternative are estimated to be $336,200, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 2 years is estimated to be $80,800, which assumes quarterly groundwater sampling. The O&M cost for the following 5 years is

estimated to be $10,100 per year, which assumes annual groundwater sampling. The net present value of 7 years of O&M costs is $121,700, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 5, including a 30 percent contingency, is $596,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Alternative 5 is one of the least expensive of the alternatives that employ active remedial measures. Additionally, this alternative is expected to meet the RAOs for the site within a reasonable time period, and is thus protective. As a result, this option has a high degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat benzene at IRP Site 9 to below significant adverse-effect levels within a reasonable timeframe.

State Acceptance. The use of enhanced bioremediation to treat groundwater at the Base has been accepted by ODEQ for relatively small-scale implementation and is expected to be acceptable for full-scale application.



Community Acceptance. The use of enhanced bioremediation is not expected to have community resistance.

5.3.1.6 IRP Site 9 - Alternative 6: In-Well Aeration with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 6 at IRP Site 9 with respect to the criteria described in Section 5.1. Figure 5-10 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative would reduce the risk posed by IRP Site 9 by reducing benzene concentrations in Shallow Zone groundwater, as well as the potential for contaminated Shallow Zone groundwater to migrate to off-site receptors.

Compliance with ARARs. This alternative is expected to reduce benzene in IRP Site 9 groundwater to below chemical-specific ARARs. Groundwater within the zone of active treatment by in-well aeration is expected to be rapidly treated to concentrations below ARARs. MNA is expected to degrade benzene in downgradient groundwater outside of the

IRP SITE 9

ALTERNATIVE 6
IN-WELL AERATION
WITH MONITORED NATURAL ATTENTUATION

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-10

radius of influence of the in-well aeration system to below ARARs, although at a rate slower than that within the active treatment zone.

Long-Term Effectiveness and Permanence. The residual risk posed by IRP Site 2 would be reduced by this alternative because the risk posed by benzene in Shallow Zone groundwater would be significantly reduced. Groundwater monitoring would be required beyond the operation of the in-well aeration system to verify attainment of the cleanup goals.

The contaminants in the downgradient areas of the site treated by MNA are expected to be destroyed within a reasonable timeframe, due to enhanced aerobic conditions from upgradient aeration. However, if long-term monitoring indicates that VOCs in this area are not degrading at an acceptable rate, expansion of the aeration system to actively treat this area would be considered.

The institutional and engineering controls implemented as part of this alternative would likely be reliable in the long term, based on current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV through Treatment. Unlike other treatment technologies discussed in this FS, this technology is based on the transfer of contaminants among media, rather than destruction. Transferring benzene from the groundwater to the activated carbon reduces the mobility and volume of the contaminants. The reduction of toxicity of the contaminants would depend on the final disposition of the spent carbon. For example, if the spent carbon is to be disposed of at a landfill, toxicity would not be reduced.

Short-Term Effectiveness. It is difficult to estimate with accuracy the time required to meet the remediation goal; however, the in-well aeration system should reduce benzene concentrations in groundwater to below treatment goals within 2 years. The area to be treated by MNA would not experience reductions at the same rate as that within the in-well aeration area. However, the risks associated with this area are much lower.

Implementability. Implementability issues identified with this alternative include installation of sub-grade piping across Base roads (if necessary), avoidance of underground utilities, and connection to Base utilities.

This technology has been shown to effectively remove VOCs from groundwater in locations with adequate subsurface flow characteristics.

However, it is still considered an innovative technology, and has not been tested as extensively as some others.

Cost. Capital and O&M costs associated with Alternative 6 are summarized in Table B-8, and detailed in Table B-13. Direct and indirect capital costs for this alternative are estimated to be $469,200, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 3 years is estimated to be $316,200, which assumes quarterly groundwater sampling and 3 years of treatment system operation. The O&M cost for the following 5 years is estimated to be $10,100 per year, which assumes annual groundwater sampling. The net present value of 8 years of O&M costs is $357,100, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 6, including a 30 percent contingency, is $1,075,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to -30 percent.

Alternative 6 is expected to meet the RAOs for the site within a reasonable time period, and would therefore be considered protective. This alternative is one of the most expensive alternatives, and therefore has a medium degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat benzene at IRP Site 9 to below significant adverse-effect levels within a reasonable timeframe.

State Acceptance. The use of in-well aeration to treat groundwater at the Base would be expected to be acceptable by ODEQ for full-scale implementation. There are no significant water quality issues related to implementation of this technology, which is a major issue with ODEQ.

Community Acceptance. The use of in-well aeration to treat groundwater at the Base would be expected to be acceptable by community residents.

5.3.2 IRP Site 9 - Comparative Analysis of Alternatives

As discussed, the above-detailed evaluation comprised an individual analysis the six RA alternatives for IRP Site 9, with respect to protectiveness, compliance with ARARs, long-term effectiveness and permanence, reduction of TMV through treatment, short-term effectiveness, implementability, cost, and treatment of hot spots. Below, the alternatives are compared and rated based on how well each satisfies

the evaluation criteria. Because all of the action alternatives involve the completion of a set of common tasks, the following comparative analysis will focus only on those actions that are in addition to the common tasks.

5.3.2.1 IRP Site 9 - Overall Protection of Human Health and the Environment

Chemically impacted groundwater at IRP Site 9 does not pose immediate risk to human health and the environment because it is not currently used. Therefore, all of the alternatives are equally protective in the immediate timeframe. However, since the exposure pathway used for this FS considers migration of impacted groundwater to other water bodies, such as deeper aquifers or surface water, the most protective alternative would be that which would most reliably, completely, and quickly remove those chemicals impacting groundwater at IRP Site 9.

Alternatives 1 and 2 are not expected to reliably, completely, or quickly reduce the benzene concentrations in IRP Site 9 groundwater to acceptable levels. The reliability of Alternative 6 is uncertain. Although a similar technology was shown to remove VOCs from groundwater extracted from the Shallow Zone at IRP Site 2, the technology proposed for Alternative 6 requires further testing. Alternatives 4 and 5 are expected to reliably and quickly reduce VOC concentrations.

The alternative most protective of human health and the environment is Alternative 3. This alternative is expected to reliably and quickly remove risks associated with benzene-impacted groundwater at IRP Site 9. Sodium persulfate has not been tested on groundwater containing benzene at the Base, but benzene is expected to be receptive to this oxidation mechanism.

5.3.2.2 IRP Site 9 - Compliance with ARARs

The ARAR that governs this FS is the federal MCL for each of the VOCs impacting groundwater, as is the case for benzene in IRP Site 9 groundwater. Alternatives 1 and 2 would not likely reduce benzene concentrations to below the MCL of 5 µg/l, and therefore would not comply with the ARAR for this compound.

Alternatives 4 and 6 have the potential to reduce benzene concentrations to below the respective ARARs.

Alternatives 3 and 5 would most reliably treat VOCs in groundwater to below ARARs. Because of its ability to aerobically degrade and the

presence of additional carbon sources (petroleum hydrocarbons) at IRP Site 9, enhanced aerobic bioremediation is expected to successfully reduce benzene to below its MCL. Benzene is also expected to effectively treated by sodium persulfate oxidation.

5.3.2.3 IRP Site 9 - Long-Term Effectiveness and Permanence

Alternatives 1 and 2 would not provide long-term effectiveness. These alternatives are not expected to reduce concentrations of benzene in groundwater at IRP Site 9 to below the significant adverse-effect level.

Alternatives 3, 4, and 5 would provide equal long-term effectiveness, provided RAOs are equally met as well. These alternatives utilize technologies that provide in situ destruction of contaminants. These technologies are not reversible and do not pose additional risks after treatment goals are met.

Alternative 6 would provide similar long-term effectiveness as that provided by Alternative 3, 4, and 5. However, rather than destroying the contaminants in situ, Alternative 6 uses a technology that strips VOCs from groundwater, and moves them above ground through sparged air, where the VOCs are subsequently destroyed. This technology is also irreversible, and poses no additional risks after treatment goals are met.

Alternative 3 and 5 are the most effective alternatives in the long term because they are the alternatives most likely to be able to reach treatment goals, therefore not requiring replacement.

5.3.2.4 IRP Site 9 - Reduction of Toxicity, Mobility, or Volume through Treatment

Alternatives 1 and 2 will not significantly reduce TMV of benzene-impacted groundwater at IRP Site 9. Some reduction of toxicity may occur through reduction of benzene concentration at localized areas. However, the mobility and volume would likely remain unchanged, or could possibly increase.

Alternatives 3, 4, 5, and 6 are expected to effectively reduce the TMV of VOC-impacted groundwater at IRP Site 2. However, Alternative 3 and 5 are expected to provide the greatest reduction.

5.3.2.5 IRP Site 9 - Short-Term Effectiveness

The short-term effectiveness of Alternatives 1 and 2 is unacceptably low, based on the length of time required to reduce benzene concentrations in

IRP Site 9 groundwater. Groundwater containing unacceptable levels of benzene could possibly migrate off-site, or down to the CRSA, within the time required to reach cleanup goals under these alternatives.

Alternatives 3, 4, 5, and 6 all provide sufficient, short-term effectiveness. These alternatives will significantly reduce VOC concentrations in groundwater in a relatively quick fashion. Alternatives 3, 4, and 5 pose slight threats to workers in the form of exposure to the injection material used for each alternative. These threats could be controlled by the use of health and safety measures. No threats to workers are expected during implementation of Alternative 6, beyond the typical mechanical dangers associated with well drilling and installation of machinery.

5.3.2.6 IRP Site 9 - Implementability

Alternatives 1 and 2 are the easiest alternatives to implement. Alternative 1 requires no action, and Alternative 2 requires only installation of additional monitoring wells, and periodic monitoring of VOCs and natural attenuation parameters. However, the reliability of these alternatives is questionable, and it would be expected that they would require replacement at a later date.

The next easiest alternatives to implement are Alternatives 3 and 5. These alternatives involve the direct-push injection of a treatment material, and progress monitoring. Neither of these alternatives are expected to require replacement.

The implementation of Alternatives 4 and 6 involve the construction of several, complex sparge wells, and a system of piping, compressors, and controls. The systems for these alternatives would require periodic monitoring, trouble shooting, and maintenance.

5.3.2.7 IRP Site 9 - Cost

Alternative 1 and 2 are the least expensive alternatives; however these alternatives fail to satisfy the protectiveness criterion because they are not expected to meet the site RAOs within a reasonable time period. These alternatives are therefore not cost reasonable. Alternatives 4 and 6 are expected to meet the site RAOs within a reasonable time period, however these are two of the most expensive alternatives. Alternatives 3 and 5 meet the same level of protectiveness as Alternatives 4 and 6, but are less expensive. Alternative 3 and 5 are therefore the most cost reasonable alternatives.

5.3.2.8 IRP Site 9 - Treatment of Hot Spots

Alternatives 1 and 2 are not expected to effectively treat the hot spot of contamination in IRP Site 9 groundwater. The implementation of either of these alternatives would potentially allow the extent of this hot spot to increase.

Alternatives 3, 4, 5, and 6 are capable of treating VOCs to below the significant adverse-effect levels. However, the expected reliability of Alternative 3 is greater than the other alternatives.

5.3.2.9 IRP Site 9 – State Acceptance

Alternatives 1 and 2 are not expected to effectively treat hot spots of contamination in groundwater at IRP Site 9 and therefore are not expected to be acceptable to ODEQ. All of the remaining alternatives would likely reduce the size of the hot spots at IRP Site 9 through treatment as required by ODEQ. However, the use of sodium persulfate injection would be scrutinized by ODEQ the most due to the injection of an oxidizing fluid into the groundwater.

5.3.2.10 IRP Site 9 – Community Acceptance

Alternatives 1 and 2 are not expected to be acceptable to the community because they are not expected to treat hot spots of contamination in groundwater at IRP Site 9 within a reasonable timeframe.

All of the remaining alternatives would likely reduce the size of the hot spots at IRP Site 9 through treatment and should generally be acceptable to community residents. However, for Alternative 3 using sodium persulfate injection it will be important to implement a monitoring program that will sufficiently allow the public to review water quality data.

5.3.3 IRP Site 9 - Preferred Alternative

Alternative 3 is the preferred alternative because it best satisfies the protectiveness criteria, and most of the remedy-selection balancing factors. Alternative 3 involves direct-push injection of sodium persulfate through the vertical extent of the Shallow Zone, combined with MNA. This alternative also includes the implementation of the common tasks

described in Section 4.5.2. By implementation of Alternative 3, the following achievements are expected:

- Human health and the environment within the locality of facility would be protected over the long term.
- The residual risk associated with VOCs in groundwater remaining after completion of this alternative would be acceptable, as described in Section 6.2.
- Base workers would be protected from exposure to VOCs in groundwater through the use of institutional and engineering controls.
- In situ oxidation using sodium persulfate would be one of the most cost-effective means of reducing concentrations of benzene in IRP Site 9 groundwater.

5.4 IRP Site 11

5.4.1 IRP Site 11 - Individual Analysis of Alternatives

The following presents an evaluation of the RA alternatives for IRP Site 11 against the evaluation criteria. The remedial alternatives evaluated for IRP Site 11 include:

- Alternative 1: No Action
- Alternative 2: MNA
- Alternative 3: In Situ Oxidation – Potassium Permanganate Injection with MNA
- Alternative 4: In Situ Oxidation – Ozone Sparging with MNA
- Alternative 5: Enhanced Bioremediation with MNA
- Alternative 6: In-Well Aeration with MNA

5.4.1.1 IRP Site 11 - Alternative 1: No Action

The following is an evaluation of the application of Alternative 1 at IRP Site 11 with respect to the criteria described in Section 5.1.

Overall Protection of Human Health and Environment. The No Action Alternative would not be protective of human health and the environment in the short-term, because the risks associated with Shallow Zone and Deep Zone groundwater are not immediately reduced, either by treatment or by implementing restrictions that would prevent exposure site groundwater, such as institutional controls. Because contaminated Shallow Zone and Deep Zone groundwater has the potential to migrate off-site, the No Action Alternative would not provide long-term protection of human health and the environment.

Compliance with ARARs. The No Action Alternative would not meet chemical-specific ARARs, because several chlorinated VOCs in Shallow Zone and Deep Zone groundwater currently exceed ARARs. The No Action Alternative would potentially reduce VOC concentrations to below respective ARARs in downgradient areas of IRP Site 11 due to natural processes. However, the higher concentration VOCs in the upgradient area of IRP Site 11 are not expected to naturally degrade to below ARARs within a reasonable timeframe.

Long-Term Effectiveness and Permanence. The No Action Alternative would not provide long-term effectiveness and permanence, because the residual risk to human and environmental receptors remaining from untreated chlorinated VOCs in Shallow Zone and Deep Zone groundwater is too great.

Reduction of TMV Through Treatment. The No Action Alternative does not include any treatment to reduce TMV. As a result, it is possible that chlorinated VOCs would continue to migrate laterally and vertically, and eventually reach off-site receptors. Biodegradation of TCE in Shallow Zone groundwater may continue to occur as observed in the past, but the natural degradation of lower-order chlorinated ethenes (cis-1,2-DCE and VC) in Shallow Zone and Deep Zone groundwater is not expected to be significant. The degradation is expected to be slower than migration, thereby increasing the volume of contaminated groundwater.

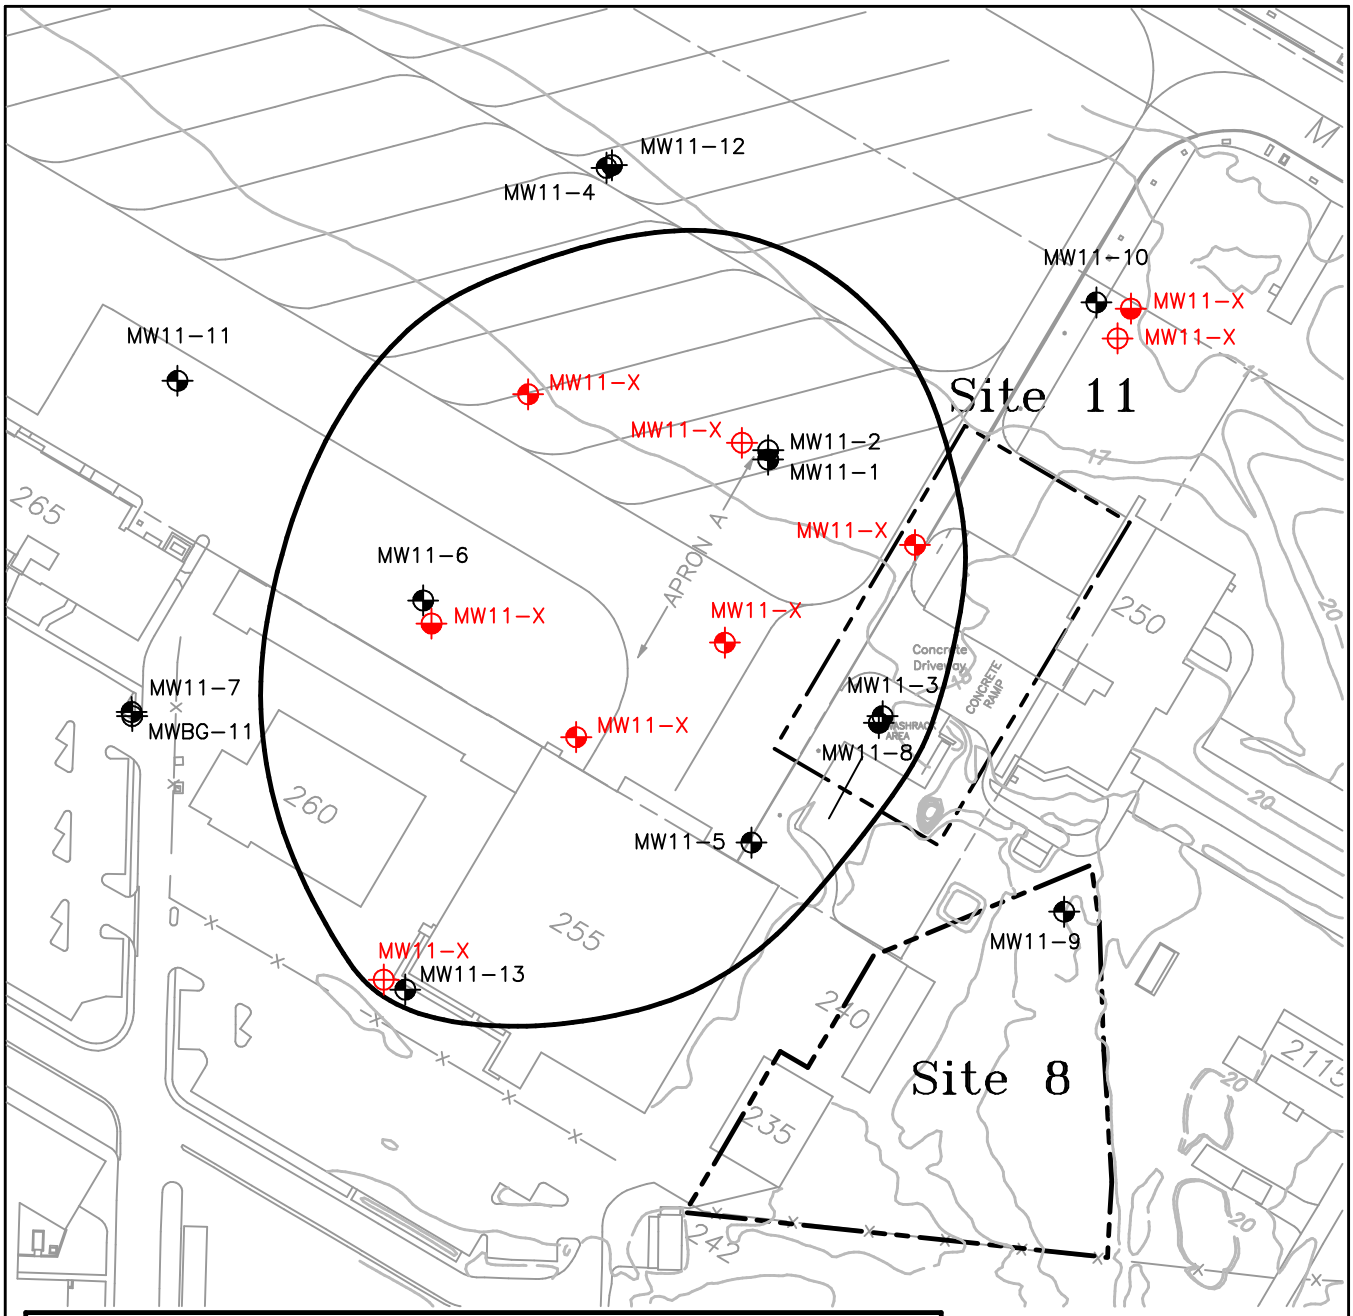
Short-Term Effectiveness. The No Action Alternative would present short-term, human health risks associated with chlorinated VOCs in groundwater at IRP Site 2. However, these risks are no greater than the existing risks at the site.

Implementability. The No Action Alternative would not incur implementation obstacles. In addition, there are no O&M requirements for the alternative.

Cost. No costs would be associated with implementing the No Action Alternative. Because this alternative is not effective in meeting the RAOs for the site, and is therefore not protective, it has a low degree of cost reasonableness.

Treatment of Hot Spots. The No Action Alternative does not meet Oregon's requirement that hot spots of contamination be treated to below the significant adverse-effect level.

State Acceptance. The No Action Alternative would not be acceptable to ODEQ. Oregon requires that hot spots such as that present in groundwater at IRP Site 11 be treated to below the significant adverse-effect level.



Community Acceptance. The No Action Alternative is not expected to be acceptable to the community. The community is active at the Base in the form of a Restoration Advisory Board (RAB), and would not be accepting of leaving an area of groundwater impacted at the level of IRP Site 11 untreated.

5.4.1.2 IRP Site 11 - Alternative 2: Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 2 at IRP Site 11 with respect to the criteria described in Section 5.1. Figure 5-11 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. The MNA Alternative would be protective of human health and the environment in the short-term. Near-future exposure to groundwater with unacceptable risk is prevented through institutional and engineering controls implemented at the Base. Groundwater with VOC concentrations above unacceptable risk levels has not migrated to any off-site receptors and is not expected to do so in the near future. However, there is long-term risk associated with off-site migration of groundwater containing VOCs.

During the Natural Attenuation Evaluation that was conducted as part of the RI (ERM 2001a) it was concluded that the degradation rate of VC is very slow. Because of this, it is possible that Shallow Zone and Deep Zone groundwater containing levels of VC above the RAOs has the potential to migrate off-site. The MNA Alternative, therefore, would also not provide long-term protection of human health and the environment.

ALTERNATIVE 2
MONITORED NATURAL ATTENTUATION
LOCATION OF MONITORING WELLS

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-11

Compliance with ARARs. The MNA Alternative does not meet chemical-specific ARARs because chlorinated VOCs in Shallow Zone and Deep Zone groundwater currently exceed ARARs and are not expected to naturally degrade to below levels determined by the chemical-specific ARARs within a time frame that is reasonable compared to that offered by other methods.

Long-Term Effectiveness and Permanence. The MNA Alternative may provide long-term effectiveness and permanence due to eventual natural degradation of VOCs below RAOs. However, this is unlikely to occur within a reasonable time period. It is uncertain if this alternative will treat groundwater to appropriate levels prior to migrating off-site, thereby violating the first RAO. This uncertainty creates the potential need to replace this remedy.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant if the ownership or leaseholder of the Base property changes.

Reduction of TMV Through Treatment. The MNA Alternative is not expected to significantly reduce the TMV of VOCs at IRP Site 11 within a reasonable timeframe. Natural biodegradation of lower order chlorinated ethenes cis-1,2-DCE and VC is not expected to be rapid. The toxicity of Shallow Zone and Deep Zone groundwater may be slowly reduced as areas of higher concentration VOCs are slowly treated. As VC is produced through reductive dechlorination of dichloroethene, the mobility will actually increase due to the increased solubility and decreased sorption tendency of VC in relation to its parent compounds. If natural degradation proves to be slower than the migration rate, the volume of contaminated groundwater may actually increase due to potential further downgradient and vertical migration of slowly degrading VOCs.

Short-Term Effectiveness. The MNA Alternative would present short-term human health risks associated with chlorinated VOCs in groundwater at IRP Site 11. The short-term risks associated with this alternative are a result of the expected duration required to meet treatment objectives. The required duration of MNA could exceed 30 years. Within that period, groundwater containing unacceptable concentrations of VOCs may migrate off-site, violating the first RAO and presenting risk to off-site receptors.

The institutional and engineering controls implemented under this alternative are expected to prevent unacceptable risk to on-site receptors, including base workers and workers implementing this RA.

Implementability. The MNA Alternative would not have implementation obstacles. The additional proposed wells will ensure the ability to monitor the effectiveness of this alternative. The technologies used for this alternative are readily available and implementable.

Cost. Capital and O&M costs associated with Alternative 2 are summarized in Table B-14 and detailed in Table B-15. Direct and indirect capital costs for this alternative are estimated to be $151,700, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first year is estimated to be $110,000, which assumes quarterly groundwater sampling. The O&M cost for the following 30 years is estimated to be $27,500 per year, which assumes annual groundwater sampling. The net present value of 31 years of O&M costs is $434,800, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 2, including a 30 percent contingency, is $763,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Because Alternative 2 does not meet the RAOs for the site within a reasonable time period, this alternative is not protective and therefore has a low degree of cost reasonableness.

Treatment of Hot Spots. Although MNA is considered a treatment technology by Oregon State, the hot spot at IRP Site 11 is not expected to be treated to concentrations below the significant adverse effect level in a timely manner under this alternative. The hot spot, defined by the extent of contaminants above respective significant adverse effect levels, could potentially expand due to migration of the source area.

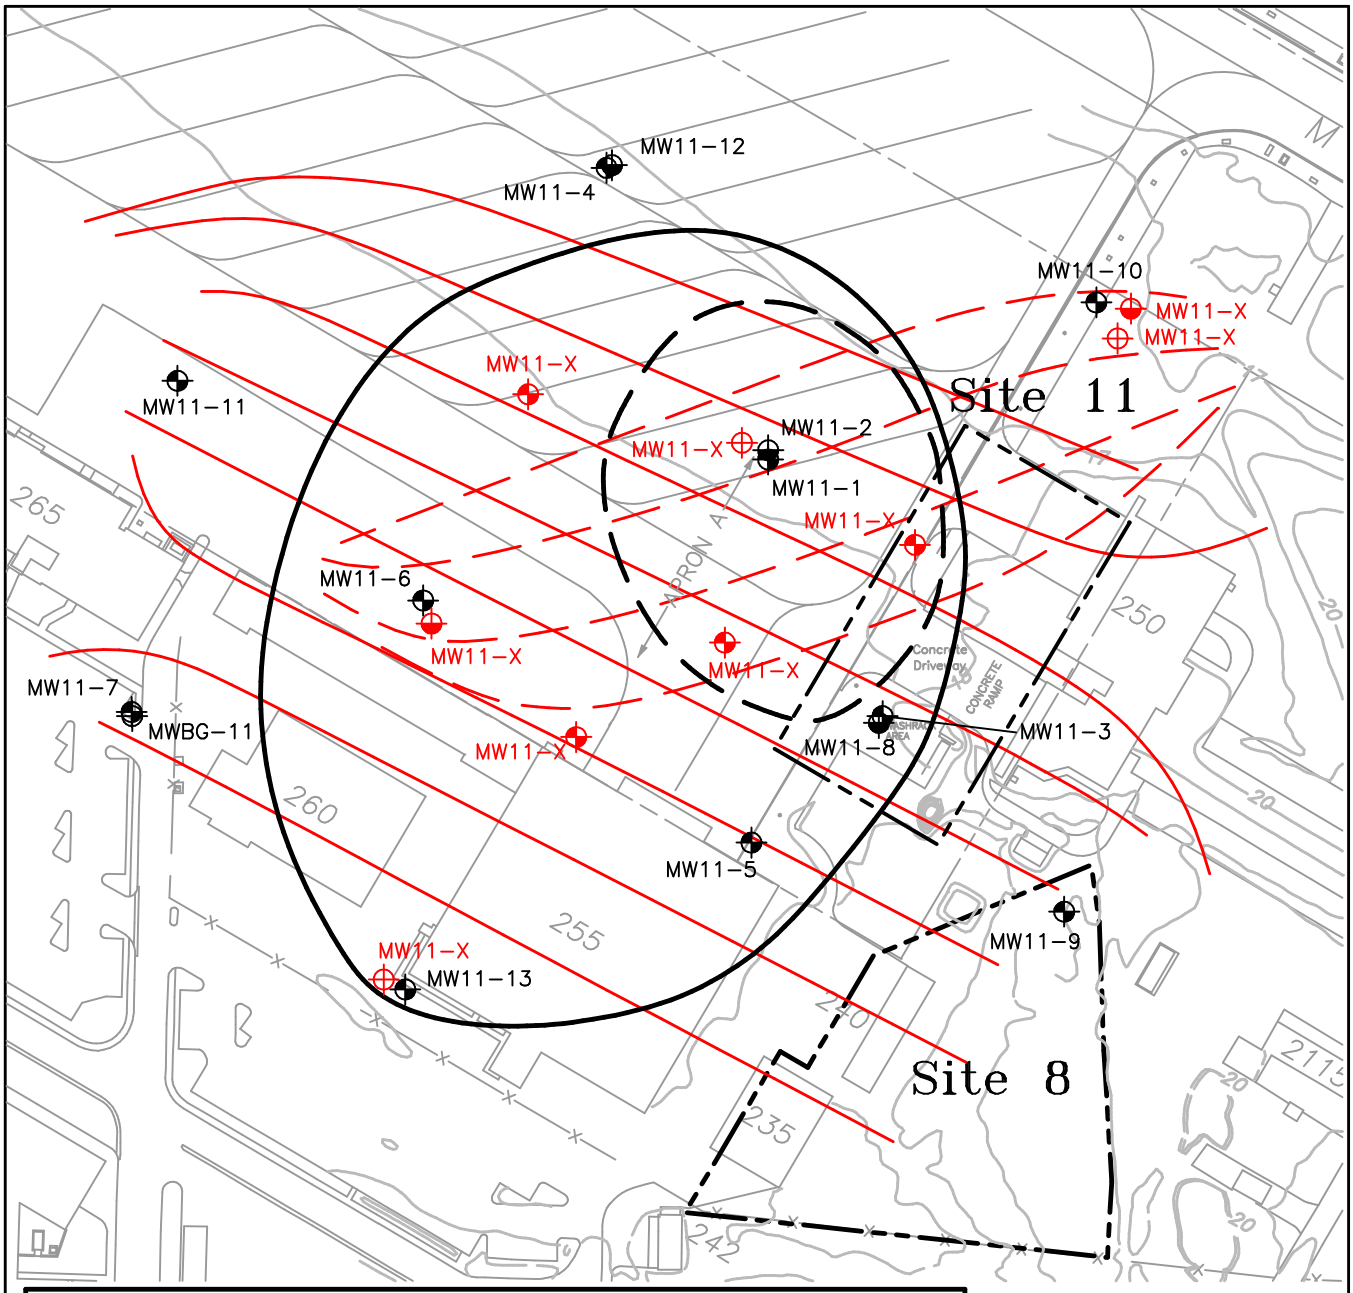
State Acceptance. The Natural Attenuation Alternative would not be expected to be acceptable to ODEQ. Oregon requires that hot spots such as that present in groundwater at IRP Site 11 be treated within a reasonable timeframe and this is not expected to occur using the Natural Attenuation alternative.

Community Acceptance. The Natural Attenuation Alternative is not expected to be acceptable to the community due to the expected duration required to meet treatment goals.

5.4.1.3 IRP Site 11 - Alternative 3: In Situ Oxidation - Potassium Permanganate Injection with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 3 at IRP Site 11 with respect to the criteria described in Section 5.1. Figure 5-12 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative is expected to effectively remove or significantly reduce the concentrations of VOCs from groundwater at IRP Site 11. The risks associated with exposure to these compounds would be reduced to an acceptable level based on the current and future land use.



Compliance with ARARs. This alternative is expected to effectively reduce the concentrations of VOCs in groundwater to below the levels set by chemical-specific ARARs.

Long-Term Effectiveness and Permanence. The residual risk posed by groundwater at IRP Site 11 would be reduced by this alternative because the contaminants associated with the risks are destroyed. Groundwater monitoring would be required for an extended period after the completion of this alternative in order to verify attainment of the RAOs.

The contaminants in the downgradient areas of the Site treated by MNA are expected to be destroyed within a reasonable time frame, due to enhanced conditions from upgradient permanganate injection. However, if long-term monitoring indicates that VOCs in this area are not degrading at an acceptable rate, potassium permanganate can be injected in additional injection wells installed in this area.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant if the ownership or leaseholder of the Base property changes.

Reduction of TMV Through Treatment. The use of potassium permanganate oxidation and MNA to treat VOCs in groundwater will result in reduced toxicity, mobility, and volume of hazardous materials in IRP Site 11 groundwater. This reduction is performed through chemical and biological destruction rather than transfer of contaminants from one media to another. The treatment process is irreversible and will result in the production of only harmless byproducts.

PORTLAND, OREGON

FIGURE 5–12

Short-Term Effectiveness. Workers performing the injection will be in contact with potassium permanganate in solid or dissolved form. Worker exposure would be minimized by the use of appropriate health and safety personal protective equipment.

Adverse effects on groundwater that is used for drinking or irrigation is not expected, as described in Section 4.4.5.1. The oxidative effects of the potassium permanganate will diminish with time as it reacts with organic material in the subsurface.

Risks associated with VOCs in groundwater are quickly reduced due to the rapid treatment resulting from permanganate oxidation. Destruction of VOCs in areas treated by potassium permanganate is expected to be complete within 1 to 2 years.

Implementability. Implementation obstacles within the zone of active remediation by potassium permanganate injection include ensuring the avoidance of underground utilities, coring through the thick concrete on the flight apron to install wells, working around secure buildings, and coordinating well installation and permanganate injection with flight operations and Base personnel. The use of directionally-drilled horizontal wells will avoid the need to install numerous vertical injection wells. However, the installation of the horizontal wells requires a great deal of precision, expertise, equipment and space, compared to conventional drilling. Closure of areas at the drilling locations may be required. This alternative has been developed to allow full use of the flight apron during construction, with the exception of the installation of a small number of monitoring wells.

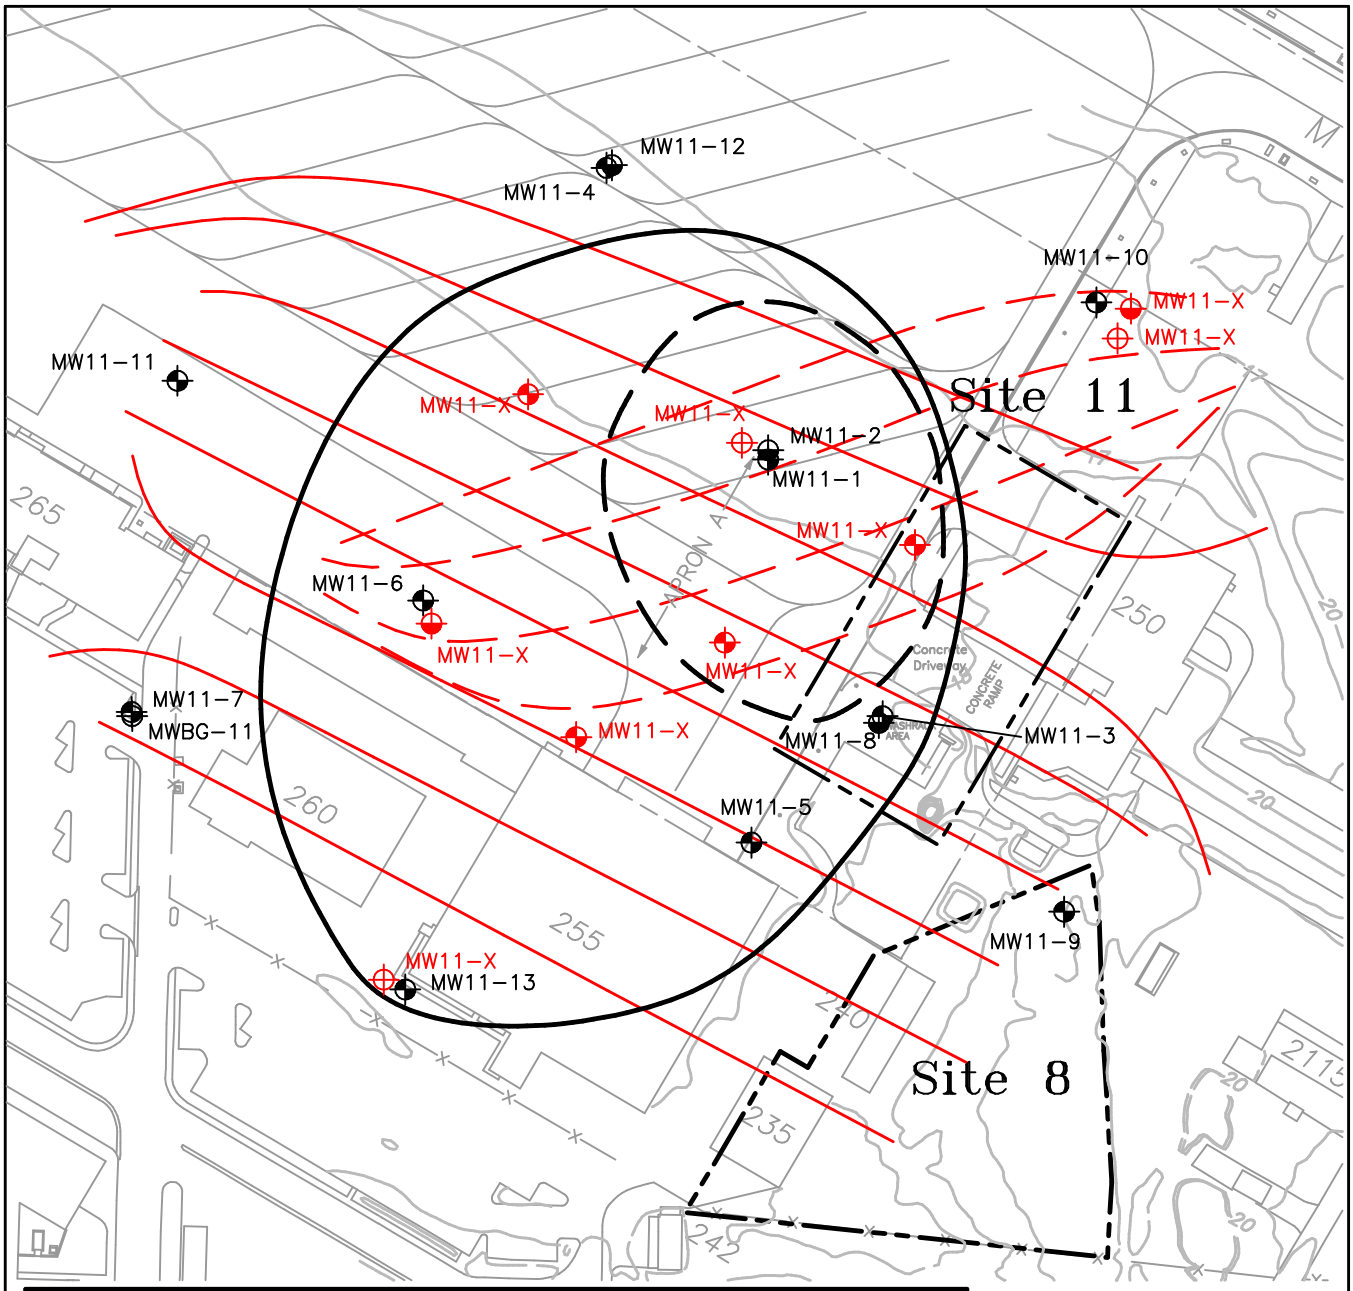
The implementability of this alternative may be inhibited by the geology at the site. Preferential flow paths and areas of low conductivity will dictate where the injected potassium permanganate will flow. This may result in small regions of an aquifer not receiving injected material. This can be overcome by performing multiple injections of potassium permanganate.

The injection of potassium permanganate will require coordination with the ODEQ UIC program. This will create scheduling delays due to ODEQ review and public participation requirements.

Cost. Capital and O&M costs associated with Alternative 3 are summarized in Table B-14 and detailed in Table B-16. Direct and indirect capital costs for this alternative are estimated to be $1,673,950, and include

all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 2 years is estimated to be $220,000, which assumes quarterly groundwater sampling. The O&M cost for the following 5 years is estimated to be $27,500 per year, which assumes annual groundwater sampling. The net present value of 7 years of O&M costs is $331,300, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 3, including a 30 percent contingency, is $2,607,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Alternative 3 is the least expensive of the alternatives that employ active remedial measures. Additionally, this alternative is expected to meet the RAOs for the site within a reasonable time period and is thus protective. As a result, this alternative has a high degree of cost reasonableness.



Treatment of Hot Spots. This alternative is expected to treat the VOCs at IRP Site 11 to below significant adverse effect levels within a reasonable timeframe.

State Acceptance. The use of potassium permanganate to treat groundwater at the Base has been accepted by ODEQ for relatively small-scale implementation and is expected to be acceptable for full-scale application. However, ODEQ approval of larger scale use of potassium permanganate injection is likely to be contingent on an appropriate monitoring and reporting plan to ensure compliance with the UIC program.

Community Acceptance. The use of potassium permanganate is expected to have some community resistance since it relies on the injection of a foreign material into the groundwater and the perception that it will cause groundwater flowing away from the site to remain purple. An appropriate monitoring and reporting system is an important component of this alternative to allow the public the opportunity to monitor water quality during the remedial action.

5.4.1.4 IRP Site 11 - Alternative 4: In Situ Oxidation - Ozonation with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 4 at IRP Site 11 with respect to the criteria described in Section 5.1. Figure 5-13 depicts the layout of the primary components of this alternative.

FIGURE 5-13

Overall Protection of Human Health and Environment. This alternative is expected to effectively remove, or significantly reduce, the VOC concentrations from IRP Site 11 groundwater. The risks associated with exposure to these compounds would be reduced to an acceptable level, based on current and future land use.

Compliance with ARARs. This alternative is expected to effectively reduce the VOC concentrations in Shallow Zone and Deep Zone groundwater to below the levels set by chemical-specific ARARs.

Long-Term Effectiveness and Permanence. The residual risk posed by groundwater at IRP Site 11 would be reduced by this alternative because the contaminants associated with the risks are destroyed. Groundwater monitoring would be required for an extended period after the completion of this alternative to verify attainment of the RAOs.

The contaminants in the downgradient areas of the site treated by MNA are expected to be destroyed within a reasonable timeframe, due to enhanced conditions from upgradient ozonation. However, if long-term monitoring indicates that VOCs in this area are not degrading at an acceptable rate, expansion of the area of ozonation would be considered.

The institutional and engineering controls implemented as part of this alternative should be reliable in the long term, based on the current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV Through Treatment. The use of ozonation and MNA to treat VOCs in groundwater will result in reduced TMV of hazardous materials in IRP Site 11 groundwater. This reduction would be performed through chemical and biological destruction, rather than transfer of contaminants among media. The treatment process is irreversible and will result in the production of only harmless byproducts.

Short-Term Effectiveness. Ozone is a strong oxidant and care must be taken to prevent worker or base employee exposure to ozone generated for injection. This would include periodic monitoring of ozone in workspace air, and enclosing and locking the ozone generator and sparge wellheads to prevent tampering.

Adverse effects on groundwater used for drinking or irrigation purposes would not be likely expected, as the oxidative effects of ozone are short-lived.

Risks associated with VOCs in groundwater are quickly reduced due to the rapid treatment resulting from ozonation. Destruction of VOCs in areas treated by ozonation is expected to be complete within 3 years.

Implementability. Implementation obstacles within the zone of active remediation include ensuring the avoidance of underground utilities, coring through the thick concrete on the flight apron to install wells, working around secure buildings, and coordinating well installation and system operation with flight operations. The use of directionally-drilled horizontal wells will avoid the need to install numerous vertical sparge wells and extensive underground piping in the flight apron area. However, the installation of the horizontal wells requires a great deal of precision, expertise, equipment, and space, compared to conventional drilling. Closure of areas at the drilling locations may be required. This alternative has been developed to allow full use of the flight apron during construction, with the exception of the installation of a small number of monitoring wells. Also, the use of horizontal wells precludes the use of in-well water-recirculating pumps that are occasionally used to increase the radius of influence of ozone sparge wells.

The implementability of this alternative may be inhibited by the site geology. Preferential flow paths and areas of low conductivity would dictate where sparged air would flow; however, this could likely be overcome by utilizing a pulsed sparging technique consisting of alternating periods of sparging with periods of rest.

The injection of ozone would require coordination with the ODEQ UIC program, which would likely will create scheduling delays due to ODEQ's review and public participation requirements.

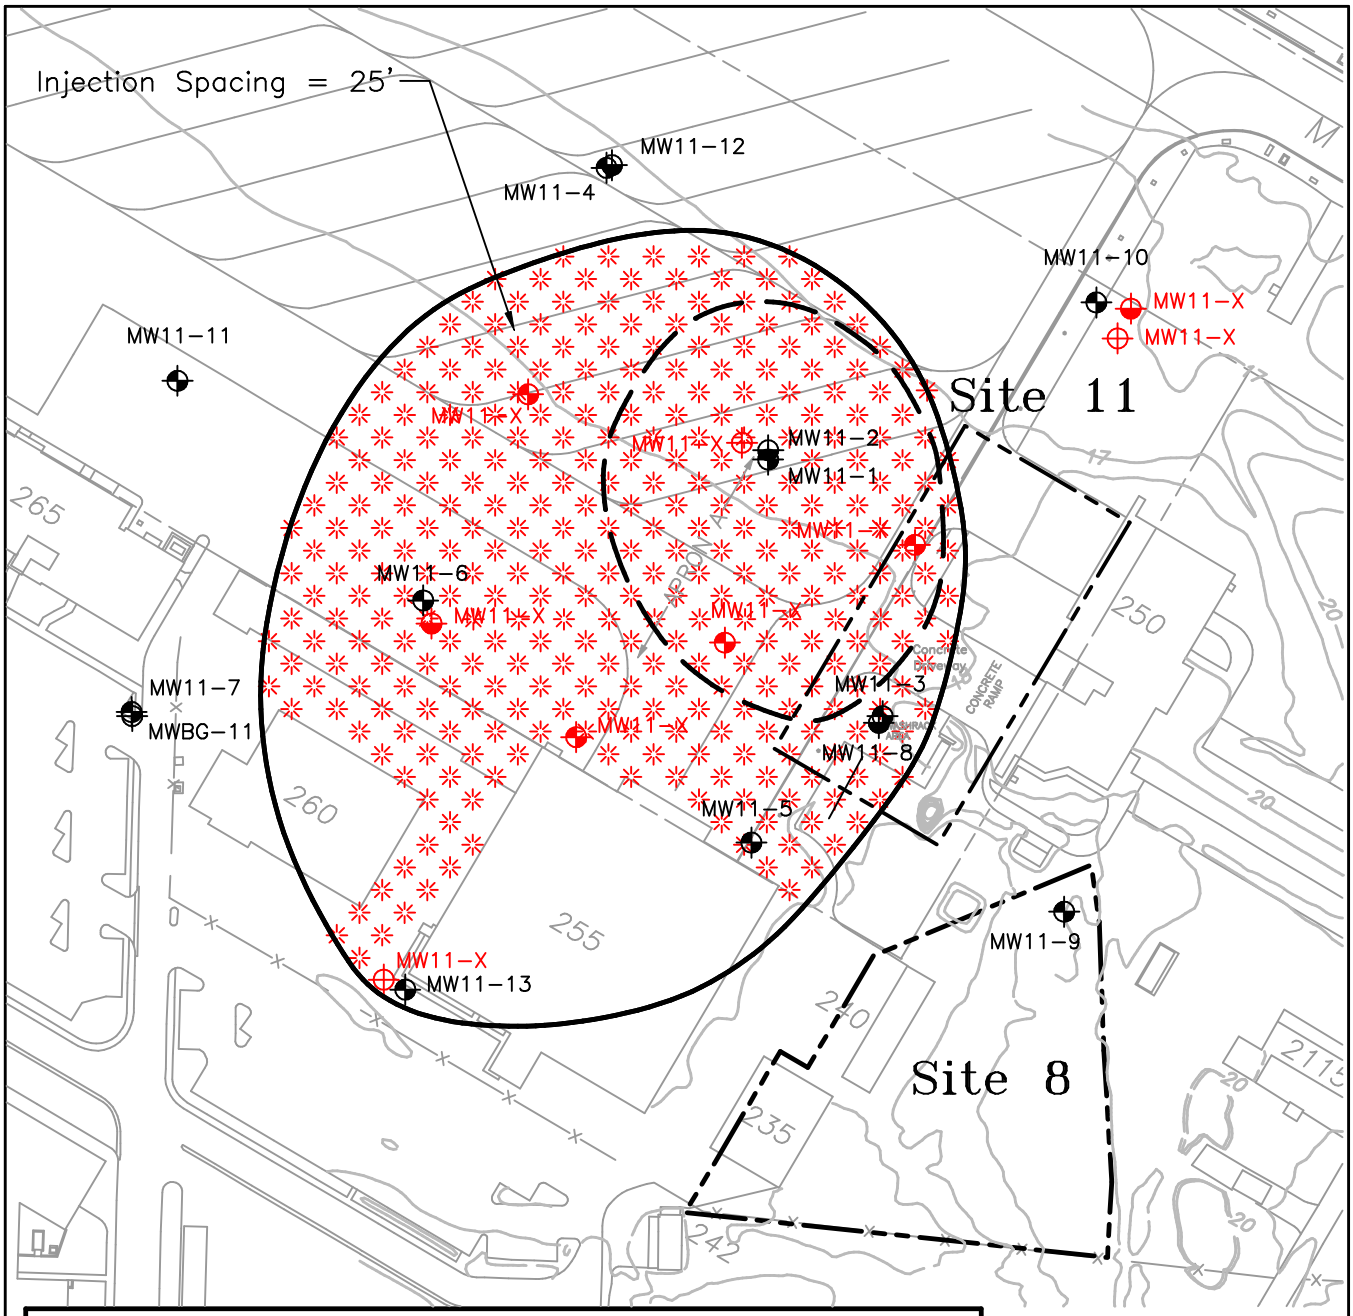
This would entail more equipment and maintenance than other alternatives. In addition, installation and monitoring of the system would require extensive labor as compared to technologies that simply involve injection and monitoring.

Cost. Capital and O&M costs associated with Alternative 4 are summarized in Table B-14 and detailed in Table B-17. Direct and indirect capital costs for this alternative are estimated to be $2,592,850, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 3 years is estimated to be $685,800, which assumes quarterly groundwater sampling and 3 years of treatment system operation. The O&M cost for the following 5 years is estimated to be $27,500 per year, which assumes annual groundwater sampling. The net present value of 8

years of O&M costs is $798,600 , which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 4, including a 30 percent contingency, is $4,409,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Alternative 4 is expected to meet the RAOs for the site within a reasonable timeframe and is thus protective. Additionally, Alternative 4 is one of the least expensive alternatives that employ active remedial measures. Therefore, it has a high degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat the VOCs at IRP Site 11 to below significant adverse-effect levels within a reasonable timeframe.



State Acceptance. The use of ozonation to treat groundwater at the Base has been accepted by ODEQ for relatively small-scale implementation and is expected to be acceptable for full-scale application. However, ODEQ approval of larger scale use of an injection technology is likely to be contingent on an appropriate monitoring and reporting plan to ensure compliance with the UIC program.

Community Acceptance. The use of ozonation is expected to have less community resistance than other injection technologies since it relies on the injection of a short-lived gas rather than a liquid. However, an appropriate monitoring and reporting system is still an important component of this alternative to allow the public the opportunity to monitor water quality during the remedial action.

5.4.1.5 IRP Site 11 - Alternative 5: Enhanced Bioremediation with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 5 at IRP Site 11 with respect to the criteria described in Section 5.1. Figure 5-14 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative is expected to effectively reduce VOCs in Shallow Zone and Deep Zone groundwater at IRP Site 11, and the risks associated with exposure to this contamination. However, the effectiveness of this alternative is uncertain, as the use of oxygen releasing materials to treat groundwater containing VC has not been performed extensively. Approximately 75 percent removal of VC was observed during a pilot test performed using ORC® at IRP Site 2 It is expected that VC and cis-1,2-DCE will

FIGURE 5-14

degrade following the creation of enhanced aerobic conditions, but it is uncertain whether the treatment will reduce concentrations to below RAOs.

This alternative is expected to take longer to begin significant reduction of VOCs versus other alternatives, because native microbes must acclimate to the enhanced environment following injection.

Compliance with ARARs. The ability of this alternative to reach ARARs through treatment is uncertain. The effectiveness of this technology at reducing VC to the very low concentrations specified by chemical specific ARARs is uncertain.

Long-Term Effectiveness and Permanence. The residual risk posed by Shallow Zone and Deep Zone groundwater at IRP Site 11 would be reduced by this alternative because the contaminants associated with the risks are degraded to harmless byproducts. Although it is uncertain if this alternative would reduce VC to below the significant adverse-effect level at the site, the resulting reduction should be sufficient to prevent off-site migration, thereby meeting the first RAO. Groundwater monitoring would be required for an extended period to verify attainment of this RAO.

The institutional and engineering controls implemented as part of this alternative would likely be reliable in the long term, based on current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV Through Treatment. Enhancing bioremediation in IRP Site 11 groundwater would reduce the TMV of VOCs. This would be accomplished through irreversible biological destruction, rather than transfer of contaminants among media. The amount of VOCs that would be degraded by enhanced bioremediation at this site is unknown. A significant reduction of VOC concentration is expected, though, which would result in significant reduction of toxicity. Mobility and volume of contaminated groundwater would also be expected to decrease.

Short-Term Effectiveness. This alternative is expected to take a short period to begin effective removal, thus delaying the reduction of risk. Natural biological activity at IRP Site 11 has been shown to be stagnant, and would require acclimation following injection of an enhancing product.

Groundwater containing unacceptable VOC concentrations has not migrated off Base, and is not expected to reach Base boundaries in the very near future. Also, the institutional and engineering controls used as part of this alternative would prevent VOC exposure at the site. These factors would likely limit the added risks related to the delayed effectiveness of this alternative.

Implementability. Implementation obstacles within the zone of active remediation include ensuring the avoidance of underground utilities, coring through the thick concrete on the flight apron for each direct-push injection location, working around secure buildings, and coordinating well installation and direct-push injection with flight operations. Certain areas at the edge of the hot spot at IRP Site 11 would not be conducive to treatment due to the presence of buildings, such as Buildings 260 and 255 at the south end of the hot spot (Figure 5-14). Coordinating the extensive coring and patching of the surface to original conditions would be difficult on the flight apron. This alternative also relies on multiple staggered injections in closely spaced locations. Coring the concrete surface at this interval may impact the structural integrity of the concrete surface. This alternative is considered infeasible based on these factors.

The treatment of groundwater by the injection of an oxygen releasing material more greatly relies on the flow of groundwater past the injection locations, than the flow of injected material into surrounding groundwater. The shallow gradient of groundwater at IRP Site 11 would limit the rate of transfer of oxygen created to the surrounding groundwater.

The injection of any material would require coordination with the ODEQ UIC program, which could likely create scheduling delays due to ODEQ's review and public participation requirements.

Cost. Capital and O&M costs associated with Alternative 5 are summarized in Table B-14, and detailed in Table B-18. Direct and indirect capital costs for this alternative are estimated to be $2,983,150, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 2 years is estimated to be $220,000, which assumes quarterly groundwater sampling. The O&M cost for the following 5 years is estimated to be $27,500 per year, which assumes annual groundwater sampling. The net present value of 7 years of O&M costs is $331,300, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 5, including a 30 percent contingency, is $4,309,000. In

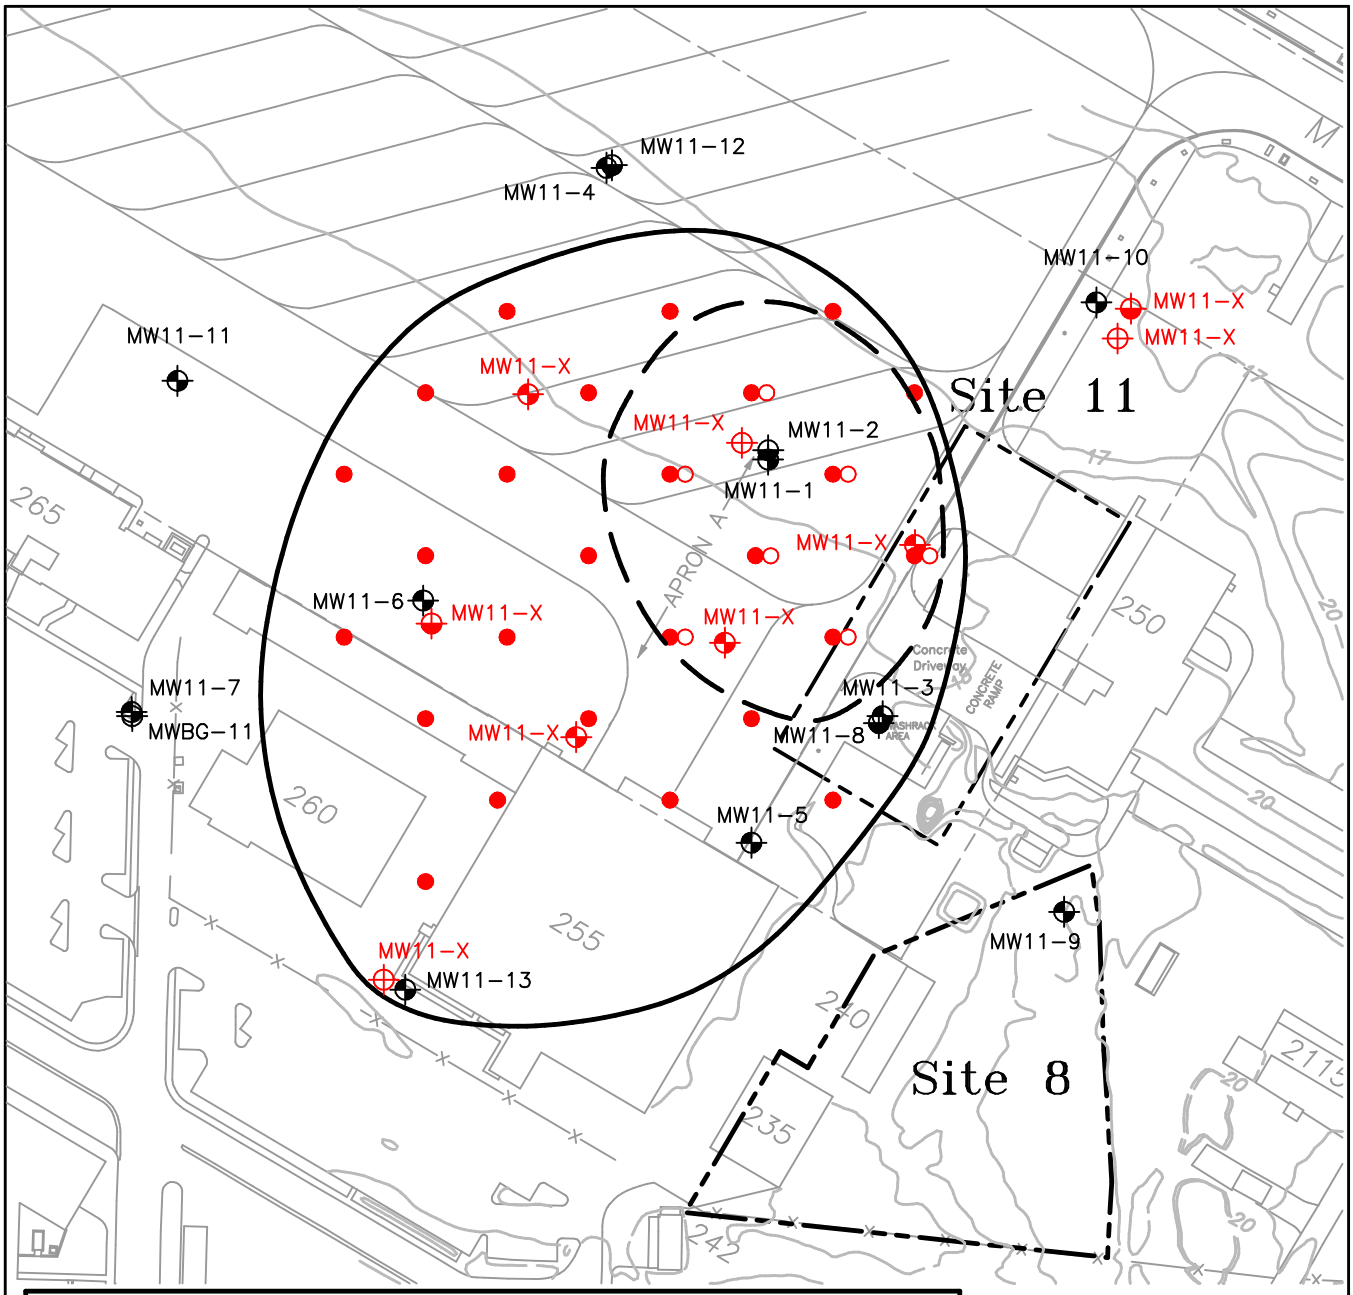
accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Alternative 5 is one of the most expensive of the alternatives that employ active remedial measures. Also, this alternative is not expected to meet the RAOs for the site in a reasonable time period, and would not therefore be considered protective. As a result, this alternative has a low degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat most VOCs at IRP Site 11 to below respective significant adverse-effect levels within a reasonable timeframe. It is unknown if VC could be treated by this method to its significant adverse-effect level of 2 µg/l (ODEQ 1998c) within a reasonable timeframe.

State Acceptance. The use of enhanced bioremediation to treat groundwater at the Base has been accepted by ODEQ for relatively small-scale implementation and is expected to be acceptable for full-scale application.

Community Acceptance. The use of enhanced bioremediation is not expected to have community resistance. However, since this technology is less established for treatment of chlorinated hydrocarbons, the community may be skeptical that it would effectively achieve cleanup goals.



5.4.1.6 IRP Site 11 - Alternative 6: In-Well Aeration with Monitored Natural Attenuation

The following is an evaluation of the application of Alternative 6 at IRP Site 11 with respect to the criteria described in Section 5.1. Figure 5-15 depicts the layout of the primary components of this alternative.

Overall Protection of Human Health and Environment. This alternative would reduce the risk posed by IRP Site 11 by reducing the VOC concentrations in Shallow Zone and Deep Zone groundwater, and the potential for contaminated groundwater to migrate to off-site receptors. The risks associated with exposure to these compounds would be reduced to an acceptable level, based on current and future land use.

Risks might be posed by regeneration or disposal of spent activated carbon associated with vapor treatment.

Compliance with ARARs. This alternative is expected to reduce VOCs in IRP Site 11 groundwater to below chemical-specific ARARs.

IRP SITE 11
ALTERNATIVE 6
IN-WELL AERATION
WITH MONITORED NATURAL ATTENUATION
PLAN VIEW OF TREATMENT SYSTEM LAYOUT

142nd FW, PORTLAND ANGB
PORTLAND INTERNATIONAL AIRPORT
PORTLAND, OREGON

FIGURE 5-15

Groundwater within the zone of active treatment by in-well aeration is expected to be rapidly treated to concentrations below ARARs. MNA is expected to degrade VOCs in downgradient groundwater outside of the radius of influence of the in-well aeration system to below ARARs, although at a slower rate than within the active treatment zone.

Long-Term Effectiveness and Permanence. The residual risk posed by IRP Site 11 would be reduced by this alternative because the risk posed by the VOCs in Shallow Zone and Deep Zone groundwater would be significantly reduced. Groundwater monitoring would be required beyond the operation of the in-well aeration system to verify attainment of cleanup goals.

The contaminants in the downgradient areas of the site treated by MNA are expected to be destroyed within a reasonable timeframe, due to enhanced aerobic conditions from upgradient aeration. However, if long-term monitoring indicates that VOCs in this area are not degrading at an acceptable rate, expansion of the system to actively treat this area would be considered.

The institutional and engineering controls implemented as part of this alternative would likely be reliable in the long term, based on current and future land-use scenarios. However, care must be taken to ensure that the controls remain in effect with each future tenant, if the ownership or leaseholder of the Base property changes.

Reduction of TMV through Treatment. Unlike other treatment technologies discussed in this FS, this technology is based on the transfer of contaminant among media, rather than destruction. Transferring the VOCs from the groundwater to the activated carbon would reduce the mobility and volume of the contaminants. The reduction of toxicity of the contaminants would depend on the final disposition of the spent carbon. For example, if the spent carbon is disposed of at a landfill, the toxicity would not be reduced. This process is irreversible if the activated carbon is handled properly.

Short-Term Effectiveness. It is difficult to estimate with accuracy the time required to achieve the remediation goal; however, based on similar scenarios, the in-well aeration system would likely reduce VOC concentrations in groundwater to below treatment goals within 3 years. The area to be treated by MNA would not experience reductions at the same rate as those within the in-well aeration area. However, the risks associated with this area are much lower.

Implementability. Implementation obstacles within the zone of active remediation include avoiding underground utilities, coring through the thick concrete on the flight apron to install wells, working around secure buildings, and coordinating well installation and system operation with flight operations. Certain areas at the edge of the hot spot at IRP Site 11 would not be conducive to treatment due to the presence of buildings (i.e., Buildings 260 and 255) at the south end of the hot spot. Installation of sub-grade wellhead connections and piping across the flight apron would also be required. Coordinating extensive cutting, trenching, pipe laying, and finishing of the concrete surface of the flight apron would be difficult. Horizontal installation of an in-well aeration system is not feasible.

Trenching, drilling, and other construction activities associated with installation of the in-well aeration system will require significant shut down of flight operations at the site. This will also effect the implementability of this alternative. This alternative is considered infeasible based on these factors.

Alternative 6 would entail more equipment and maintenance than other alternatives. In addition, installation and monitoring of the system would require extensive labor as compared to technologies that simply involve injection and monitoring.

Cost. Capital and O&M costs associated with Alternative 6 are summarized in Table B-14, and detailed in Table B-19. Direct and indirect capital costs for this alternative are estimated to be $3,287,050, and include all equipment, materials, contractor services, labor, project administration, and project management required for implementation. The O&M cost for the first 3 years is estimated to be $902,100, which assumes quarterly groundwater sampling and 3 years of treatment system operation. The O&M cost for the following 5 years is estimated to be $27,500 per year, which assumes annual groundwater sampling. The net present value of 8 years of O&M costs is $985,200, which assumes a discount rate of 7.5 percent. This discount rate was selected based on ODEQ guidance. The total estimated cost for Alternative 6, including a 30 percent contingency, is $5,554,000. In accordance with USEPA and ODEQ Guidance, these estimates are expected to be accurate to +50 to –30 percent.

Alternative 6 is expected to meet the RAOs for the site within a reasonable time period, and is therefore protective. However, this alternative is the most expensive alternative, and therefore has a medium degree of cost reasonableness.

Treatment of Hot Spots. This alternative is expected to treat the VOCs at IRP Site 11 to below significant adverse-effect levels within a reasonable timeframe.

State Acceptance. The use of in-well aeration to treat groundwater at the Base would be expected to be acceptable by ODEQ for full-scale implementation. There are no significant water quality issues related to implementation of this technology, which is a major issue with ODEQ.

Community Acceptance. The use of in-well aeration to treat groundwater at the Base would be expected to be acceptable by community residents.

5.4.2 IRP Site 11 - Comparative Analysis of Alternatives

The above-detailed evaluation consisted of an individual analysis of the six RA alternatives for IRP Site 11, with respect to protectiveness, compliance with ARARs, long-term effectiveness and permanence, reduction of TMV through treatment, short-term effectiveness, implementability, cost, and treatment of hot spots. Below, the alternatives are compared, and rated based on how well each satisfies the evaluation criteria. Because all of the action alternatives involve the completion of a set of common tasks, the following comparative analysis will focus only on those actions that are in addition to the common tasks.

5.4.2.1 IRP Site 11 - Overall Protection of Human Health and the Environment

Chemically impacted groundwater at IRP Site 11 does not pose immediate risk to human health and the environment because the groundwater is not currently used. Therefore, all of the alternatives are equally protective in the immediate timeframe. However, since the exposure pathway used for this FS considers migration of impacted groundwater to other water bodies, such as deeper aquifers or surface water, the most protective alternative would be that which would most reliably, completely, and quickly remove those chemicals impacting groundwater at IRP Site 11.

Alternative 1 and 2 are not expected to reliably, completely, or quickly remove the chlorinated VOCs impacting groundwater at IRP Site 11. The reliability of Alternative 6 is uncertain; however, a similar technology was shown to remove VOCs from groundwater extracted from Shallow Zone groundwater at IRP Site 2. However, the recirculation-well aspect of this technology proposed for this FS has not been tested at the Base. Alternative 5 is expected to reliably and quickly remove risks associated with chlorinated VOCs impacting groundwater at IRP Site 11, as shown

during the IRAC treatability test performed at IRP Site 2. However, Alternative 5 is not expected to sufficiently reduce VOC concentrations to meet the RAOs. It is expected that the effectiveness of enhanced bioremediation would diminish, as the amount of VOCs and other organic material decreases.

Alternative 4 is expected to reliably and quickly reduce concentrations of VOCs. This alternative is expected to take longer than some of the other alternatives.

Alternative 3 is most protective of human health and the environment. Like alternatives based on other technologies, this alternative has been proven to quickly destroy chlorinated VOCs in Base groundwater. This alternative is much more reliable and complete than others because potassium permanganate provides residual treatment capacity, and the effectiveness of this technology is more easily monitored.

5.4.2.2 IRP Site 11 - Compliance with ARARs

The ARAR that governs this FS is the federal MCL for each of the chlorinated VOCs impacting groundwater, as is the case for IRP Site 11 groundwater. Alternatives 1, 2, and 5 are not expected to comply with this ARAR, as VC concentrations are not expected to be reduced below the MCL of 2 µg/l for this compound.

Alternatives 4 and 6 have the potential to reduce VOC concentrations to below the respective ARARs. The in-well aeration technology of Alternative 6 has not been completely tested at the Base. Ozone sparging has been tested at the Base during the IRAC test, with some success.

Alternative 3 would most likely reliably treat VOCs in groundwater to below ARARs. Because of the complete destruction of VOCs that occurs upon contact with potassium permanganate solution, this alternative could likely be tailored in the field to provide complete destruction of VOCs impacting groundwater at IRP Site 11.

5.4.2.3 IRP Site 11 - Long-Term Effectiveness and Permanence

Alternatives 1 and 2 do not provide long-term effectiveness. These alternatives are not expected to reduce VOC concentrations in groundwater at IRP Site 11 to below the significant adverse-effect levels.

Alternatives 3, 4, and 5 would provide equal long-term effectiveness, provided RAOs are equally met. These alternatives utilize technologies that provide in situ destruction of contaminants. These technologies are not reversible, and do not pose additional risks after meeting treatment goals.

Alternative 6 would provide similar long-term effectiveness, to that of Alternative 3, 4, and 5. However, rather than destroying the contaminants in situ, Alternative 6 would utilize a technology that strips VOCs from groundwater, and moves them above ground through sparged air, where they are then destroyed. This technology is also irreversible, and poses no additional risks after treatment goals are met.

Alternative 3 would be the most effective alternative in the long term, because of the greater residual ability of potassium permanganate to destroy VOCs.

5.4.2.4 IRP Site 11 - Reduction of Toxicity, Mobility, or Volume through Treatment

Alternatives 1 and 2 would not significantly reduce TMV of VOC-impacted groundwater impacted at IRP Site 11. Some reduction of toxicity may occur through reduction of VOC concentration at localized areas. However, the mobility and volume would likely remain unchanged, or possibly increase.

Alternatives 3, 4, and 6 are expected to effectively reduce the TMV of VOC-impacted groundwater at IRP Site 11. Alternatives 3 and 4 are expected to provide the greatest reduction.

Alternative 5 is expected to significantly reduce the toxicity of VOC-impacted groundwater. However, since this technology is not expected to provide effective treatment at lower concentrations, the reduction of the volume of impacted groundwater might not be as significant as the reduction expected with Alternatives 3, 4, and 6.

5.4.2.5 IRP Site 11 - Short-Term Effectiveness

The short-term effectiveness of Alternatives 1 and 2 is unacceptably low, based on the length of time required to reduce VOC concentrations in IRP Site 11 groundwater. VOCs could possibly migrate off-site, or down to the CRSA, within the time required to reach cleanup goals under these alternatives.

Alternatives 3, 4, 5, and 6 all provide sufficient, short-term effectiveness. These alternatives would significantly reduce VOC concentrations in groundwater in a relatively quick fashion. Alternatives 3 and 4 would pose threats to workers in the form of exposure to the oxidizers potassium permanganate and ozone. These threats could likely be controlled by the use of health and safety measures. No threats to workers are expected during implementation of Alternative 6, beyond the typical mechanical dangers associated with well drilling and machinery installation.

5.4.2.6 IRP Site 11 - Implementability

Alternatives 1 and 2 would be the easiest alternatives to implement. Alternative 1 requires no action, and Alternative 2 requires only installation of additional monitoring wells, and periodic monitoring of VOCs and natural attenuation parameters. However, the reliability of these alternatives is questionable, and it would be expected that they would require replacement at a later date.

Implementation of the remaining four alternatives would be difficult at IRP Site 11 due to the thick concrete present on the flight apron. Alternatives 5 and 6 are not feasible, due to the number of direct-push injections or well installations required (each of which require coring and patching of the concrete surface of the flight apron at IRP Site 11). Neither of these alternatives can be implemented using horizontal installation techniques similar to Alternatives 3 and 4. Oxygen-releasing material (Alternative 5) cannot be injected into a well similar to potassium permanganate, and thus requires a new injection location for each of the several applications. In-well aeration (Alternative 6) cannot be utilized with horizontal wells.

The most implementable alternatives are Alternatives 3 and 4 due to the use of horizontal drilling and installation methods. These techniques will allow implementation of these alternatives with little disruption of the flight apron concrete or flight operations. Alternative 4 would be more difficult to implement that Alternative 3 due to the amount of equipment (e.g., ozone generators, sparge points, etc.) required for operation. In addition, the installation of the SVE system would require significant additional horizontal drilling not required as part of the other alternatives.

5.4.2.7 IRP Site 11 - Cost

Alternative 1 and 2 are the least expensive alternatives, however these alternatives fail to satisfy the protectiveness criterion because they are not

expected to meet the site RAOs within a reasonable time period. These alternatives are therefore not cost reasonable. Alternative 5 is also not expected to meet the RAOs within a reasonable time period. As a result, this alternative is not the most cost reasonable. Alternatives 4 and 6 are both expected to meet the RAOs within a similarly reasonable time period, however these alternatives are more expensive than Alternative 3, and therefore are not the most cost reasonable. Alternative 3 is expected to meet remedial objectives and it is the least expensive of the alternatives that employ active remedial measures. Alternative 3 is therefore the most cost reasonable.

5.4.2.8 IRP Site 11 - Treatment of Hot Spots

Alternatives 1 and 2 would not likely effectively treat hot spots of contamination in groundwater at IRP Site 11. The implementation of either of these alternatives would potentially allow the extent of this hot spot to increase.

All of the remaining alternatives would likely reduce the size of the hot spot at IRP Site 11 through treatment. It is uncertain whether Alternative 5 would be effective at treating VOCs, particularly VC, to below the significant adverse effect level.

Alternatives 3, 4, and 6 are potentially capable of treating VOCs to below the significant adverse-effect levels; however, the expected reliability of Alternative 3 would be greater than the other alternatives.

5.4.2.9 IRP Site 11 – State Acceptance

Alternatives 1 and 2 are not expected to effectively treat hot spots of contamination in groundwater at IRP Site 11 and therefore are not expected to be acceptable to ODEQ. All of the remaining alternatives would likely reduce the size of the hot spots at IRP Site 11 through treatment as required by ODEQ. However, the use of potassium permanganate injection would be scrutinized by ODEQ the most due to the injection of an oxidizing fluid into the groundwater.

5.4.2.10 IRP Site 11 – Community Acceptance

Alternatives 1 and 2 are not expected to be acceptable to the community because they are not expected to treat hot spots of contamination in groundwater at IRP Site 11 within a reasonable timeframe.

All of the remaining alternatives would likely reduce the size of the hot spots at IRP Site 11 through treatment and should generally be acceptable to community residents. However, for Alternative 3 using potassium permanganate injection it will be important to implement a monitoring program that will sufficiently allow the public to review water quality data.

5.4.3 IRP Site 11 - Preferred Alternative

Alternative 3 is the preferred alternative because it satisfies the protectiveness criteria and remedy-selection balancing factors. Alternative 3 is also the most cost reasonable alternative and is implementable due to the ability to utilize horizontal injection wells.

Alternative 3 involves injecting potassium permanganate through several horizontal injection wells screened in the Shallow Zone and Deep Zone, combined with MNA. This alternative also includes the implementation of the common tasks described in Section 4.5.2. By implementation of Alternative 3, the following is expected to be achieved:

- Human health and the environment within the locality of facility would be protected over the long term.
- The residual risk associated with VOCs in groundwater remaining after completion of this alternative would be acceptable, as described in Section 6.2.
- Base workers would be protected from exposure to VOCs in groundwater through the use of institutional and engineering controls.
- Potassium Permanganate injection would be the most cost-effective means of reducing concentrations of VOCs in groundwater at IRP Site 11.

The EE/CA program described previously in Sections 2.8.1 and 3.11.4 is expected accomplish some of the components of the preferred alternative for IRP Site 11. The implementation of the EE/CA program will involve the injection of potassium permanganate into Shallow Zone groundwater using the same horizontal injection technique described in this FS. The purpose of the groundwater EE/CA is to immediately implement a non-time critical groundwater remedy at IRP Site 11.

The groundwater EE/CA will involve injection of potassium permanganate into Shallow Zone groundwater impacted by the highest

concentrations of VOCs. Horizontal injection wells will be used for injection. The initial area of treatment for the EE/CA is a small portion of that proposed in this FS. The first phase of the groundwater EE/CA will involve treating the area of Shallow Zone groundwater currently impacted by approximately 100 µg/l of combined VC and cis-1,2-DCE using potassium permanganate injection. Following completion of the first phase of the EE/CA, the conditions at IRP Site 11 will be reevaluated to determine if further treatment or a different treatment technology is necessary.

SECTION 6.0

RECOMMENDATIONS

This section summarizes the recommended RA alternatives for the IRP sites at the Base and presents a residual risk assessment. The RRA provides an assessment of the potential risk to human health and the environment, which might posed following the completion of the RAs at IRP Sites 2, 9, and 11.

6.1 Recommended Remedial Action Alternatives

6.1.1 IRP Site 1

As described in Section 3.1.4, the risks associated with soil at IRP Site 1 were deemed acceptable for all land-use scenarios, and therefore no further action related to soil is recommended at this location. As previously discussed, VOC-impacted groundwater within IRP Site 1 should be addressed as a portion of the plume originating from IRP Site 2, rather than as a separate groundwater plume. Accordingly, remedial alternatives developed for VOCs in IRP Site 2 groundwater will include the area of the plume that has migrated to IRP Site 1.

6.1.2 IRP Site 2

The risks associated with soil at IRP Site 2 were deemed acceptable for all land-use scenarios, and therefore no further action related to soil at this location is recommended.

As described in Section 5.2.3, Alternative 3, In Situ Oxidation - Potassium Permanganate Injection with MNA, is considered the preferred alternative for remediation of VOC-impacted groundwater at IRP Site 2 as it best satisfies the protectiveness criteria and the remedy-selection balancing factors. By implementation of Alternative 3, the following is expected to be achieved:

- Human health and the environment within the locality of facility would be protected over the long term.
- The residual risk associated with VOCs in groundwater remaining after completion of this alternative would be acceptable, as described in Section 6.2.
- Base workers would be protected from VOC exposure in groundwater through the use of institutional and engineering controls.
- Permanganate injection would be the most cost-effective means of reducing VOC concentrations in groundwater at IRP Site 2.

6.1.3 IRP Site 3

As described in Section 3.3.4, the risks associated with soil at IRP Site 3 were deemed acceptable for all land-use scenarios, and therefore no further action related to soil at this location is recommended. Further, VOC-impacted groundwater within IRP Site 3 should be addressed as a portion of the plume originating from IRP Site 2, rather than as a separate groundwater plume. Remedial alternatives developed for VOCs in IRP Site 2 groundwater will include the area of the plume that has migrated to IRP Site 3.

6.1.4 IRP Site 4

The baseline risk assessment performed during the RI (ERM 2001a) indicated that both the estimated carcinogenic risk and the noncarcinogenic hazard are acceptable for construction workers under USEPA and ODEQ guidelines. Additionally, contaminants detected in surface water and sediment in the Main Drainage Ditch do not pose unacceptable risks to potential on- or off-site ecological receptors. However, because off-site habitats along the Columbia Slough are considered to be of moderate-to-high value to wildlife, surface water monitoring should be continued to evaluate the potential for contaminants to migrate off-site via the Main Drainage Ditch. Based on recommendations from ODEQ, a Level II ecological risk assessment is planned to further evaluate potential risks to ecological receptors at the Main Drainage Ditch. Based on the results of this assessment, further action may be warranted at the Main Drainage Ditch.

6.1.5 IRP Site 5

The baseline risk assessment indicated that both the estimated carcinogenic risks and the noncarcinogenic hazards are acceptable for Base workers, construction workers, reservists, hypothetical on-site residents, and by extension, off-site residents, under USEPA and ODEQ guidelines. Consequently, no further action is recommended for soil or groundwater at this location.

6.1.6 IRP Site 7

The baseline risk assessment performed during the RI (ERM 2001a) indicated that the total estimated carcinogenic risk and noncarcinogenic hazard for Base workers, construction workers, reservists, hypothetical on-site residents, and by extension, off-site residents, are acceptable under USEPA and ODEQ guidelines. Ecological risks to the IRP Site 7 Ditch and Columbia Slough are not expected, based on the results of the Level I scoping assessment and groundwater monitoring.

The constituents detected in groundwater at IRP Site 7 are isolated detections and do not indicate persistent groundwater contamination. The risk associated with these groundwater detections is acceptable based on all anticipated land and water use scenarios. However, several groundwater samples in which PAHs were not detected were analyzed using detection limits greater than risk-based action levels, which may have underestimated associated risk. It is therefore recommended that one round of groundwater samples be collected at IRP Site 7 and analyzed using a lower detection limit to ensure that detectable concentrations of PAHs are not present. No further remedial action is recommended for this site at this time.

Regarding soil at IRP Site 7, on-site residential soil exposures are not anticipated due to current and planned industrial land use of the Portland ANGB property. In addition, because the potential risks associated with industrial soil exposures were determined to be acceptable, no further action is recommended for soil.

6.1.7 IRP Site 8

The baseline risk assessment indicated that the estimated noncarcinogenic hazards are acceptable for Base workers, construction workers, reservists, hypothetical on-site residents, and by extension, off-site residents, under

USEPA and ODEQ guidelines. Consequently, no further action is recommended for soil or groundwater at this location.

6.1.8 IRP Site 9

The baseline risk assessment indicates that the total estimated carcinogenic risk for hypothetical on-site residents exceeds USEPA and ODEQ acceptable levels, primarily as a result of assumed exposures to benzene and PAHs in groundwater under this scenario. Additionally, the carcinogenic risk associated with benzo(a)pyrene in soil under the on-site residential scenario exceeds the ODEQ benchmark for acceptable risk associated with an individual constituent. The noncarcinogenic hazard for hypothetical on-site residents also exceeds both USEPA and ODEQ guidelines, primarily as a result of benzene in groundwater. By extension of the results for the on-site residential scenario, the potential future risks to off-site residents related to the possible off-site migration and residential use of contaminated groundwater also exceed USEPA and ODEQ criteria.

On-site residential soil exposures are not anticipated due to the current and planned future industrial land use of the Portland ANGB property. Because the potential risks associated with industrial soil exposures were determined to be acceptable, no further action is recommended for soil.

As described in Section 5.3.3, the preferred RA for IRP Site 9 is Alternative 3, In Situ Oxidation – Sodium Persulfate Injection with MNA. This alternative best satisfies the protectiveness criteria and the remedy-selection balancing factors. By implementation of Alternative 3, the following is expected to be achieved:

- Human health and the environment within the locality of facility would be protected over the long term.
- The residual risk associated with VOCs in groundwater remaining after completion of this alternative would be acceptable, as described in Section 6.2.
- Base workers would be protected from exposure to VOCs in groundwater through the use of institutional and engineering controls.
- Persulfate Oxidation would be a cost-effective means of reducing benzene concentrations in groundwater at IRP Site 9.

6.1.9 IRP Site 10

The baseline risk assessment indicated that both the estimated carcinogenic risks and the noncarcinogenic hazards are acceptable for Base workers, construction workers, reservists, hypothetical on-site residents, and by extension, off-site residents, under USEPA and ODEQ guidelines. Consequently, no further action is recommended for soil or groundwater at this location.

6.1.10 IRP Site 11

The baseline risk assessment indicated that the total carcinogenic risk and noncarcinogenic hazard for hypothetical on-site residents exceed both USEPA and ODEQ levels of acceptable risk, as a result of assumed exposures to groundwater under this scenario. By extension of the results for the on-site residential scenario, the potential future risks to off-site residents related to the possible off-site migration and residential use of contaminated groundwater also exceed USEPA and ODEQ criteria. The residual soil contamination that exists near the water table in the area of the former washrack represents a potential continuing source of groundwater contamination.

Soil remaining following the 1999 soil removal action that contains elevated VOCs should be remediated. The SVE system that was partially installed adjacent to the excavated area during the removal action should be completed and placed in operation to provide treatment for the contaminated soil. SVE should provide effective removal of VOCs through volatilization and enhanced aerobic bioremediation through aeration.

As described in Section 5.4.3, the preferred alternative for remediating groundwater at IRP Site 11 is considered Alternative 3, In Situ Oxidation – Potassium Permanganate Injection with MNA. This alternative satisfies the protectiveness criteria and the remedy-selection balancing factors, and is the most protective alternative that is reasonably implementable at IRP Site 11. By implementation of Alternative 3, the following is expected to be achieved:

- Human health and the environment within the locality of facility would be protected over the long term.
- The residual risk associated with VOCs in groundwater remaining after completion of this alternative would be acceptable as described in Section 6.2.

- Base workers would be protected from exposure to VOCs in groundwater through the use of institutional and engineering controls.

- Permanganate injection would be one of the most cost-effective means of reducing VOC concentrations in groundwater at IRP Site 11.

6.2 Residual Risk Assessment

In accordance with ODEQ requirements (ODEQ 1998b), this FS includes a RRA to evaluate the potential risks associated with constituents remaining in groundwater following completion of the proposed remedial activities at IRP Sites 2, 9, and 11. This section describes the methodology used to develop the RRA and presents the results of the analysis.

As described in the ODEQ FS guidance (ODEQ 1998b), the protectiveness of the preferred remedial alternative is demonstrated through an RRA. An RRA is typically performed to provide one of the following evaluations, based on site-specific conditions:

- A quantitative assessment of the potential risk resulting from concentrations of untreated waste or treatment residuals remaining at a subject facility at the conclusion of any treatment or excavation and off-site disposal activities, taking into consideration current and reasonably likely future land- and water-use scenarios and the exposure assumptions used in the baseline risk assessment; or

- A qualitative or quantitative assessment of the adequacy and reliability of any institutional or engineering controls to be used for management of treatment residuals and untreated hazardous substances remaining at a subject facility.

Each of the above-referenced assessments is described in the following subsections.

6.2.1 Residual Risks Following Treatment

The first component of an RRA uses standard risk assessment methods to estimate the potential risk at a particular site following remediation. This step requires the determination of residual concentrations for COCs for groundwater. As discussed below, the estimation of residual groundwater concentrations can be difficult, and requires that assumptions be made regarding treatment effectiveness. One option for

estimating residual contaminant concentrations in groundwater involves measuring concentrations of concern in an area(s) immediately outside of the treatment area following completion of the RA. However, it can be reasonably predicted that at the Portland ANGB IRP sites, concentrations measured immediately outside the RA areas would not be constant through the long duration of remediation. Indeed, it is likely that these concentrations would begin to decrease at some point in the future, as a result of both reduced concentrations within the treatment areas and the effects of natural attenuation.

Alternatively, residual contaminant concentrations could be estimated based on the cleanup goals for each of the target compounds. However, this method typically results in a significant overestimate of residual risk at sites where there are multiple target analytes with significantly different concentrations and treatment goals, as is the case at IRP Site 2, as described below.

At IRP Site 2, the target compounds are TCE; cis-1,2-DCE; trans-1,2-DCE; and VC. The cleanup level for the treatment area at this site corresponds to the respective MCLs for the individual target compounds (5 µg/l for TCE; 70 µg/l for cis-1,2-DCE; 100 µg/l for trans-1,2-DCE; and 2 µg/l for VC). The percent removal required to achieve the cleanup level for VC is higher than that required for trans-1,2-DCE. At this particular site, the VC concentrations are relatively high as compared to the cleanup level for this compound. It is reasonable to assume that trans-1,2-DCE will be treated at a rate similar to VC, given the similarities in chemical properties exhibited by the two compounds. Thus, the residual concentration of trans-1,2-DCE would likely be far below its cleanup level. It follows that using the cleanup level for trans-1,2-DCE to calculate residual risk would be unnecessarily conservative.

The method used to calculate residual contaminant concentrations in this RRA addresses the limitations associated with the previous example. At each IRP site, the percent removal necessary to achieve the chemical-specific cleanup goal was calculated for each compound. Subsequently, the highest removal rate required to reach a defined cleanup level was applied to the maximum concentrations of the other compounds to calculate the maximum residual concentrations of all target analytes at a given IRP site. For example, if the concentrations of the four target compounds listed in the previous paragraph were all 200 µg/l, it was assumed that all compounds would be treated with 99 percent efficiency to reach a concentration of 2 µg/l. This residual concentration is equal to the cleanup goal for VC and is less than the cleanup goal for each of the other compounds. The initial concentrations and cleanup levels

used for these calculations, together with the resulting residual concentrations, are presented in Table 6-1.

6.2.1.1 Exposure Assessment

As described in Section 4.2, the exposure pathways used for this FS consist of residential use (i.e., for drinking, showering, etc.) of groundwater extracted from the CRSA in the vicinity of the WEA by municipal water supply recipients, and ingestion of groundwater extracted from the CRSA within the Base boundary by Base workers. However, for the purposes of the RRA, it was assumed that shallow, on-site groundwater was used for residential water supply. This assumption is consistent with exposure scenarios evaluated in the baseline human health risk assessment (presented in the Final RI Report, ERM 2001a) and with ODEQ's requirement for considering all beneficial uses for groundwater. In considering this scenario, two points deserve emphasis:

- The residential use of shallow groundwater on-site represents a hypothetical exposure, and
- The actual use of shallow groundwater for residential supply can be prevented by the implementation of institutional controls.

The cleanup goals used for treatment at the Portland Base correspond to the MCLs for the individual COCs. These cleanup goals are consistent with the requirements of the National Oil and Hazardous Substances Pollution Contingency Plan (NCP, USEPA 1990). In addition, these cleanup goals are expected to prevent off-Base or downward migration of groundwater impacted by contaminant concentrations above that which would produce unreasonable risk to potential groundwater users or other receptors. Finally, these cleanup goals are protective of on-site exposure pathways such as the migration of VOCs from groundwater into ambient or indoor air.

6.2.1.2 Toxicity Assessment

The toxicity data used in the RRA were consistent with data used to perform the risk assessment calculations presented in the Final RI Report (ERM 2001a)

TABLE 6-1

Residual Risk Calculations

142nd FW, Portland ANGB, Portland, Oregon

Constituent	Cleanup Goal (MCL)	Maximum Treatment Zone Groundwater Concentration	Percent Removal Required to Achieve Cleanup Goal (%)	Calculated Maximum Residual Groundwater Concentration	Tap Water PRG (carcinogenic effects)	Carcinogenic Risk	Tap Water PRG (noncarcinogenic effects)	Noncarcinogenic Hazard Index
IRP Site 2								
Vinyl Chloride	2	984	99.8%	2.0	0.041	5E-05	72	0.03
Trichloroethene	5	639	99.2%	1.3	1.6	8E-07	37	0.04
cis-1,2-Dichloroethene	70	724	90.3%	1.5			61	0.02
trans-1,2-Dichloroethene	100	800	87.5%	1.6			120	0.01
					Total Risk	**5E-05**	**Total HI**	**1E-01**
IRP Site 9								
Benzene	5	1200	99.6%	5	0.35	1E-05	1.1E+01	0.45
					Total Risk	**1E-05**	**Total HI**	**5E-01**
IRP Site 11								
Vinyl Chloride	2	92.5	97.8%	2	0.041	5E-05	72	0.03
cis-1,2-Dichloroethene	70	108	35.2%	2.3			61	0.04

NOTES:

1E-02 - 0.01

HI - Hazard Index

MCL - Maximum Contaminant Level (Enforceable Level) (USEPA, February, 1996, Drinking Water and Health Advisories)

PRG - Preliminary Remediation Goal (USEPA Region 9, 2000, Region 9 Preliminary Remediation Goals)

Note - Cleanup levels, constituent concentrations, and preliminary remediation goals are expressed in units of micrograms per liter.

6.2.1.3 Risk Characterization

The calculation of residual risks followed the basic approach used for the baseline human health risk assessment presented in the Final RI Report (ERM 2001a) and is consistent with ODEQ risk assessment guidance (ODEQ 2000). The specific steps used to calculated residual risks are described below. The numeric values and calculations described are shown in Table 6-1.

- The target compounds for each IRP site are listed, along with their respective cleanup goals. The cleanup goal for each of the target compounds is the MCL. These target compounds represent the most widely detected and highest concentration compounds for the IRP site in question.

- Next, the maximum treatment zone concentrations detected during the October 2000 groundwater monitoring event are listed for the target compounds.

- Then, the maximum treatment zone concentration for each compound is compared to the corresponding cleanup goal to obtain a percent removal required to reach the cleanup goal at the location with the highest concentration.

- Applying the highest required percent removal at each site to all of the target compounds at that site, a maximum residual concentration was calculated for each target compound. These values represent upper bound estimates of the residual contaminant concentrations following completion of treatment, assuming destruction of each compound at approximately the same rate. This assumption is reasonable in light of the fact that the COCs are chemically similar and are expected to responds similarly to treatment.

- Tap water PRGs developed by USEPA Region 9 (2000) were identified for each constituent. For constituents with both carcinogenic and noncarcinogenic effects (i.e., VC, TCE, and benzene), tap water PRGs were identified based on both toxicity endpoints. Tap water PRGs are risk-based screening levels that may be used to address potential risks associated with the use of water for residential supply. These levels consider potential exposures associated with both water ingestion and inhalation of volatile constituents.

- Using the estimated residual concentrations, potential carcinogenic risks were calculated according to the following formula:

Risk = (Calculated Maximum Residual Groundwater Concentration / PRG) x (1×10^{-6})

- The residual HI was estimated for each noncarcinogenic constituent, according to the following formula: HI = (Calculated Maximum Residual Groundwater Concentration / PRG)

- The total excess lifetime carcinogenic risk was then calculated as the sum of the constituent risks; similarly, the total HI was calculated as the sum of the constituent hazard indices. These calculations were performed for IRP Sites 2, 9, and 11 separately.

- As shown in Table 6-1, the total excess lifetime carcinogenic risk[2] is 5×10^{-5} for IRP Site 2, 1×10^{-5} for IRP Site 9, and 5×10^{-5} for IRP Site 11. All of these risks are within the range of acceptable risk defined by USEPA in the NCP (1990). The estimated risks for one or more constituents at each IRP site exceed ODEQ requirements (1998d) for individual constituent risk. In addition, the cumulative risks exceed ODEQ requirements (1998d) for total risk at IRP Sites 2 and 11. However, it must be emphasized again that these estimated risks are based on a hypothetical exposure scenario, and that the use of shallow ground water will be prevented through the implementation of institutional controls.

- As shown in Table 6-1, the total noncarcinogenic hazard indices are all less than one, and, thus, no adverse health effects are anticipated as a result of the defined conditions of exposure. The estimated hazard indices are all considered acceptable under USEPA and ODEQ guidelines.

The risks calculated for this RRA represent hypothetical risks associated with the use of shallow groundwater within the treatment area for residential water supply. This is a far more conservative scenario than that represented by the exposure pathways developed in Section 4.2 of this FS. It would be more realistic to estimate risk based on the potential concentrations reaching groundwater in the CRSA, the source of groundwater for the exposure pathways. A solute transport model is currently being developed for the Portland ANGB. This model will provide a mechanism for estimating a potential future concentration of VOCs in the CRSA at the three IRP sites mentioned above, based on the

[2] A risk of 1×10^{-6} represents an upper bound probability of one in one million that an excess carcinogenic response will occur during an individual's lifetime as a result of the defined conditions of exposure.

calculated residual concentrations in the treatment area. Until these calculations can be performed, the residual risks based on the exposure pathways considered for this FS can not accurately be evaluated.

6.2.2 Adequacy or Reliability of Institutional and Engineering Controls

The institutional and engineering controls presented as part of the recommended remedial alternatives for IRP Sites 2, 9, and 11 are intended to prevent human exposure to groundwater containing unacceptable levels of VOCs. These controls were developed into the tasks presented in Section 4.5.2 to be implemented with each RA. These tasks, if implemented immediately and effectively, will adequately reduce the risk of exposure to groundwater containing VOCs. This is performed through the restriction of access to site groundwater for extraction and during site activities. Health and safety provisions prevent exposure to workers during subsurface construction activities. Groundwater monitoring provides a means of detecting VOC-impacted groundwater that may migrate off the Base.

The reliability of these controls is dependent on their ability to be quickly implemented and effectively maintained. The reliability of some controls, such as deed and zoning controls is uncertain because they will require coordination with local government, the Port of Portland, and the Base. However, these controls are less crucial since they would primarily be used to control activities on the Base property at the time that the ANG vacates the Base. The recommended remedial action will likely be complete at that time and controls would serve to limit access to groundwater containing contaminants at levels only slightly above unacceptable risk levels. Controls implemented by the Base, such as groundwater monitoring, health and safety controls, and access restrictions would be more reliable. These activities are currently implemented on some level at the Base and would be simple to upgrade to the level required by this FS.

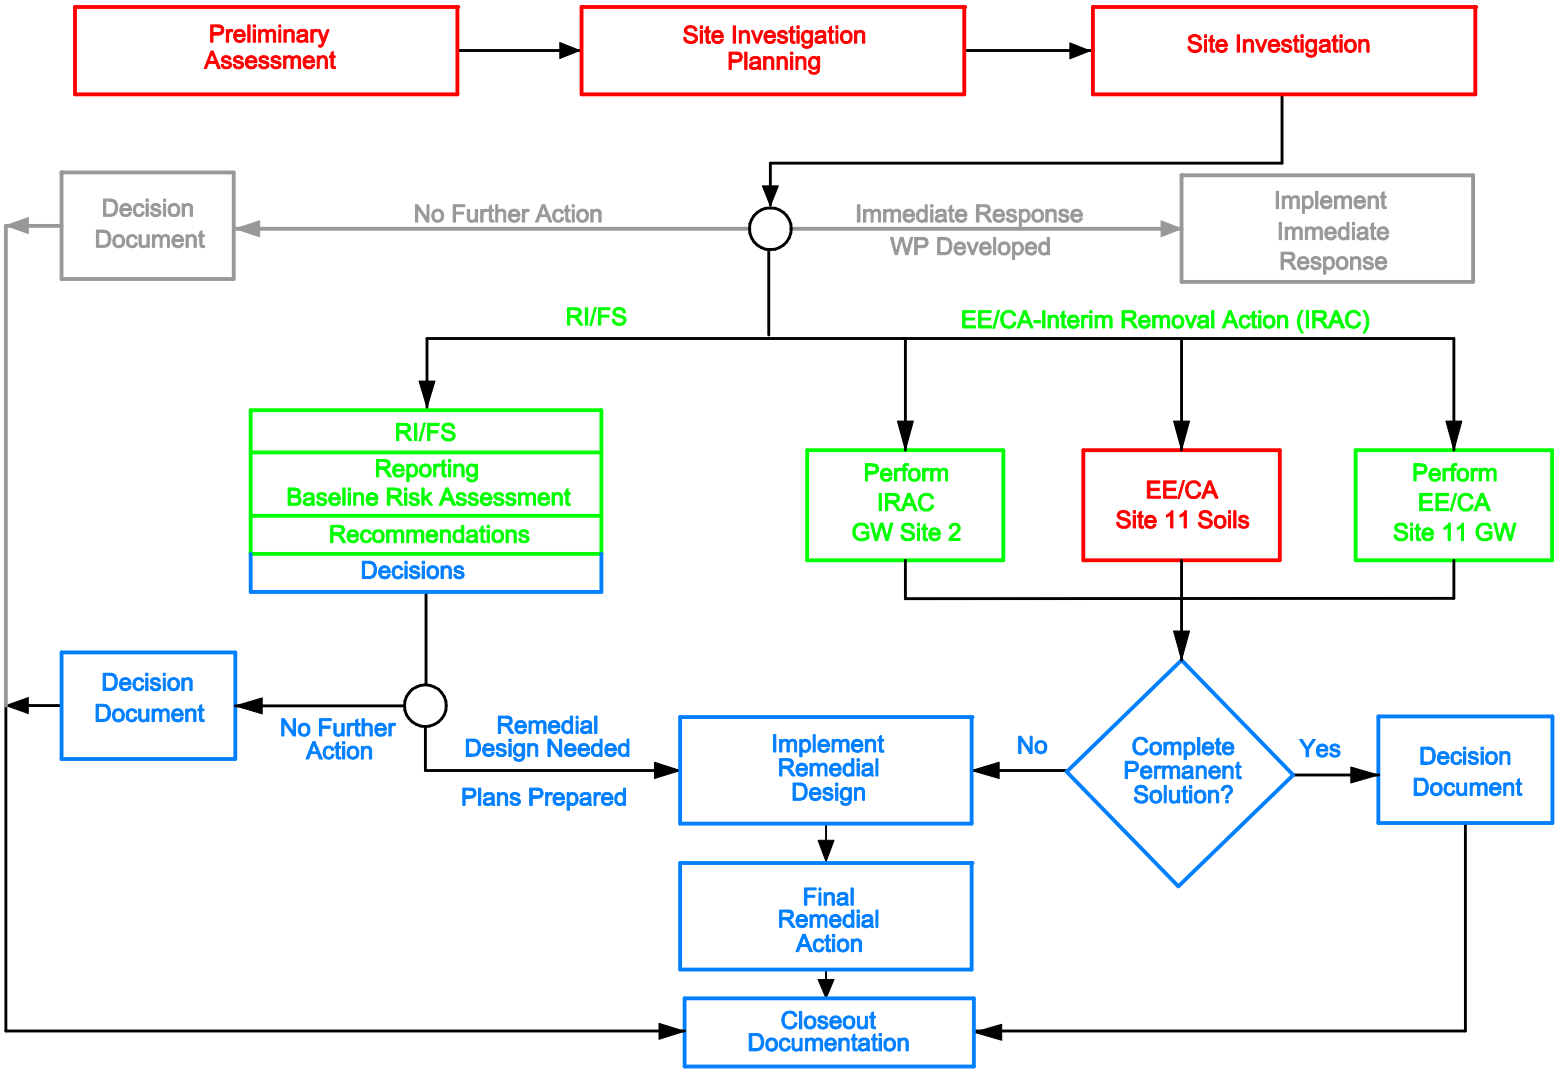
INSTALLATION RESTORATION PROGRAM SUMMARY

APPENDIX A

INSTALLATION RESTORATION PROGRAM SUMMARY



Installation Restoration Program Summary

The Defense Environmental Restoration Program (DERP) was established in 1984 to promote and coordinate efforts for the evaluation and cleanup of contamination at Department of Defense (DOD) installations. On 23 January 1987, Presidential Executive Order 12580 was issued which assigned the responsibility for carrying out DERP within the overall framework of the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 and the Superfund Amendments and Reauthorization Act of 1986 to the Secretary of Defense. The Installation Restoration Program (IRP) was established under DERP to identify, investigate, and remediate contamination at DOD installations. The IRP focuses on cleanup of contamination associated with past DOD activities to ensure that threats to public health are eliminated and to restore natural resources for future use.

The IRP decision process is separated into phases as illustrated in Figure A-1. The phases of the IRP process that have been performed at the Portland Air National Guard Base (Portland ANGB) are defined and described in general terms below.

Preliminary Assessment

A Preliminary Assessment (PA) was conducted at the Portland ANGB in 1987. A PA consists of personnel interviews, a records search, and site inspections to identify and evaluate past disposal and/or spill sites that might pose a threat to human health or the environment. Previously undocumented information is obtained through the interviews. The records search focuses on obtaining information from the following sources:

EXPLANATION

Red - Task Completed
Gray - Not Applicable
Green - Ongoing Task
Blue - Future Task

ERM

ANG PORTLAND PROJECT OVERVIEW

142nd FW, Portland ANGB
Portland, Oregon

Figure A-1

60997001.dwg, 10/04/00

- Aerial photographs;
- Installation plans;
- Facility inventory documents;
- Lists of hazardous materials used and hazardous wastes generated;
- Subcontractor reports;
- Correspondence;
- Material Safety Data Sheets;
- Federal/state agency reports on endangered or threatened species and critical habitats; and
- Other relevant documents from local government offices and standard reference sources.

As a result of the PA completed at the Portland ANGB, IRP Sites 1 through 8 were identified as potentially contaminated sites. Additional investigation was recommended for Sites 1, 2, 3, 4, 5, 7, and 8; No Further Action (NFA) was recommended for Site 6.

Site Investigation

A Site Investigation (SI) was conducted at the Portland ANGB in 1989. An SI consists of field sampling to determine whether contamination is present at the sites identified during the PA. The SI also includes a preliminary (screening) assessment of potential risks to human health and the environment.

The activities performed during the SI generally fall into three categories: screening, confirmation, and optional activities. Screening activities are conducted to gather preliminary data on each site. Confirmation activities include specific media sampling and laboratory analysis to confirm the presence or absence of contamination, chemical concentrations, and the potential for contaminant migration. Information obtained during the SI is also used to define the hydrology, geology, and soil characteristics of the sites. The data collected during the PA and SI may be sufficient to

reach a decision point for a site, such as: no further IRP action is warranted; prompt removal of contaminants is necessary; or further IRP work is required.

The general approach for the SI is to sequence the field activities so that data are acquired and used as the field investigation progresses. This is done to determine the presence or absence of contamination in a relatively short period of time, optimize data collection and data quality, and minimize costs.

As a result of the SI completed at the Portland ANGB, contamination above applicable regulatory levels was confirmed at IRP Sites 2, 4, and 5. Contaminants also were detected at IRP Sites 1, 3, and 7. Geophysical anomalies, possibly indicating disturbed soil, were detected at IRP Site 8; no samples were collected at Site 8. Following the SI, IRP Sites 10 and 11 were established based on analytical results from samples collected by Air National Guard personnel.

Remedial Investigation

A two-part Remedial Investigation (RI) was conducted at the Portland ANGB between 1995 and 2000. Phase I of the RI was conducted in 1995 and 1996, and Phase II was conducted from 1998 through 2000. The objectives of the RI are to determine the nature and extent of contamination, quantify potential threats to human health and the environment, and provide a basis for determining the response actions to be considered (e.g., NFA, Feasibility Study [FS], Remedial Design (RD), and/or Remedial Action [RA]).

Field activities performed during the RI include the installation of soil borings and groundwater monitoring wells and the collection and analysis of water, soil, and/or sediment samples. Hydrogeologic studies are conducted to characterize stratigraphy, groundwater flow directions and rates, and the potential for contaminant migration. Careful documentation and quality control procedures are implemented during RI field activities to ensure the validity of the collected data.

A baseline risk assessment is conducted to evaluate the potential threats to human health and the environment in the absence of any RA. The baseline risk assessment provides the basis for determining whether remediation may be necessary to mitigate such threats.

The RI results in the recommendation of one or more of the following response actions at each IRP site:

- NFA: The results of investigations do not indicate the presence of contamination posing an unacceptable risk to human health or the environment. Therefore, no further IRP action is warranted and a Decision Document is typically prepared to close the site.

- Long-Term Monitoring (LTM): The results of investigations do not indicate the presence of sufficient contamination to justify costly remediation. LTM may be recommended to detect possible future changes in conditions.

- Engineering Evaluation/Cost Analysis (EE/CA): The results of investigations indicate the presence of sufficient contamination to justify remediation. An EE/CA may be recommended to compare the effectiveness and costs of removal action alternatives.

- FS: The results of investigations confirm the presence of contamination that may pose a threat to human health or the environment. An FS may be recommended to establish remedial action objectives and develop remedial alternatives.

Engineering Evaluation/Cost Analysis

An EE/CA was conducted at the Portland ANGB in 1998 to address contaminated soil at IRP Site 11. At any time during an IRP project, an EE/CA can be implemented to evaluate remedial options for cleaning up contamination. An EE/CA can be completed for all non-time-critical removal actions that are not addressed by an FS. The purpose of the EE/CA is to: (1) satisfy environmental review and administrative requirements for removal actions; (2) provide a framework for evaluating and selecting alternative remediation technologies; and (3) select a remedy that significantly and permanently reduces toxicity, mobility, or volume of hazardous contaminants and is cost-effective.

An EE/CA is similar to an RI/FS but is less comprehensive because remediation is presumed to be necessary; it is often completed as a parallel effort to an RI/FS. Activities associated with the EE/CA include the following:

- Preparation of an Approval Memorandum that identifies the need for an EE/CA;
- Preparation of an EE/CA report that establishes removal action objectives and identifies and analyzes removal action alternatives; and
- Preparation of an Action Memorandum that recommends the preferred removal action alternative.

The end result of the EE/CA is the selection of the most appropriate removal action alternative with concurrence by state or Federal regulatory agencies. The EE/CA conducted at the Portland ANGB provided the necessary information to complete an Interim Remedial Action (IRA) (soil removal action) at IRP Site 11 in 1999.

Feasibility Study

Based on the results of the RI and a review of state and Federal regulatory requirements, an FS may be prepared to develop, screen, and evaluate alternatives for the remediation of contaminated media. The overall objectives of the FS include developing and evaluating remedial alternatives and selecting a remedy that is protective of human health and the environment, considers applicable or relevant and appropriate requirements, satisfies the preference for a treatment that significantly and permanently reduces toxicity, mobility, or volume of hazardous contaminants as a principal element, and maximizes cost-effectiveness.

Activities associated with the FS include the following:

- Development of remedial alternatives;
- Preliminary screening of alternatives;
- Detailed analysis of alternatives;
- Comparative analysis of alternatives; and
- Recommendation of the preferred remedial alternative in an FS report.

The end result of the FS is the selection of the most appropriate remedial alternative with concurrence by state or Federal regulatory agencies.

Remedial Design

RD involves the development and approval of the engineering plans and drawings required to implement the selected cleanup remedy identified in an EE/CA or FS. RD for the Portland ANGB was conducted in 1998 and 1999 as part of the IRA (soil removal action) performed at IRP Site 11 in September 1999.

Remedial Action

The RA phase is the actual implementation of a selected cleanup remedy. An RA may be conducted as an interim measure (i.e., an IRA), or following completion of an FS. The objective of the RA is to eliminate risks associated with environmental contamination or, at a minimum, to reduce the risks to acceptable levels. Examples of remedial alternatives that might be implemented include covering a landfill with a low-permeability cap, pumping and treating contaminated groundwater, installing a new water distribution system, and monitoring or augmenting in-situ bioremediation of contaminated soil or groundwater. In some cases, after the RA has been completed, LTM may be conducted as a precautionary measure to detect possible contaminant migration or to document the effectiveness of remediation.

An IRA (soil removal action) was conducted at the Portland ANGB in September 1999. Approximately 260 cubic yards of contaminated soil in the Site 11 source area (former washrack and oil/water separator) were excavated and treated off site. It is anticipated that other RAs will be conducted to address contaminated groundwater at the Base.

Immediate Action Alternatives

It may be determined at any point during the IRP process that a contaminated site poses an immediate threat to human health or the environment, thus necessitating prompt action to reduce the threat. Immediate action, such as limiting access to the site, capping or removing contaminated soils, or providing an alternative water supply, may suffice as effective control measures. Sites requiring immediate action maintain IRP status in order to determine the need for additional RA or LTM after the immediate action is completed. Immediate actions may be implemented during any phase of an IRP project.

APPENDIX B

COST TABLES

TABLE B-1

List of Assumptions Used in Cost Estimation
142nd FW, Portland ANGB, Portland, Oregon

Item	Value		
Indirect Costs			
Contractor Overhead & Profit	15%	TDC	
Engineering and Construction Oversight	15%	TDC	
Health and Safety Costs	3%	TDC	
Project Management & Administration	10%	TDC	
Annual O&M Replacement Costs	3%	TDC	
General Contingency	30%	Cap and O&M costs	
Well Installation and Sampling			
Site 11 Cost Multiplier (for airport concrete)	1.2		
Well Installation Costs (incl. labor & expenses)	*Sites 2 & 9*	*Site 11*	
Shallow Zone Monitoring Well Cost	$5,000	$6,000	
Deep Zone Monitoring Well Cost	$7,000	$8,400	
CRSA Monitoring Well Cost (incl. telescoping drill method)	$10,000	$12,000	
Shallow Zone Ozone Sparging Well Cost	$7,000	$8,400	
Deep Zone Ozone Sparging Well Cost	$9,800	$11,800	
Shallow Zone Injection Well Cost	$3,500	$4,200	
Deep Zone Injection Well Cost	$4,900	$5,900	
Horizontal Injection Well Cost (per foot)	$100	$120	
Horizontal Well Costs			
Horizontal Well Contractor Mobilization		$45,000

1.0 INTRODUCTION

A preliminary assessment (PA) site visit was conducted by BB&E, Inc. (BB&E) from August 26 – 27, 2015 at the Portland Air National Guard (ANG) Base (the Base), home of the 142nd Fighter Wing in Portland, Multnomah County, Oregon. The site location is shown on Figure 1. The Base is located immediately adjacent and south of the Port of Portland International Airport (PDX) and occupies approximately 245 acres of land leased from the Portland Port Authority (PPA) (ANG, 2013).

The purpose of the visit was to identify potential sites of historic environmental releases of perfluorinated compounds, specifically from Aqueous Film Forming Foam (AFFF) usage and storage, as shown on Figure 2. Prior to the site visit, BB&E conducted research of any documented Fire Training Areas (FTAs) in operation since 1970, or any other use or release of AFFF in accordance with the Final Perfluorinated Compound (PFC) Preliminary Assessment Work Plan (BB&E, 2015). During the site visit, BB&E conducted personnel interviews, reviewed on-site documentation, and toured each potential site.

Individuals contributing to this PA effort included the following:

Roger Rein – Oregon Air National Guard (ORANG), Base Environmental Manager

Harry Danberg – ORANG, Engineering

Michael Godsey – ORANG, Real Property

Rick Fogel – ORANG, Deputy Fire Chief

Lieutenant Nate Osborne – ORANG, Base Fire Department

Thomas Albright – ORANG, Base Plumber

Aviva Johnston – ORANG, Natural Resource Specialist

John LeCarno – ORANG, Base Electrician and Alarms Specialist

Sections 2.0 and 3.0 of this report outline the potential PFC sources identified on the Base property during the records review and site visit, while Section 4.0 provides conclusions and

recommendations for potential follow-on actions. References are included in Section 5.0. Representative photos of the subject sites taken during the site visit are attached as Appendix A. Interview questions and records of communication are presented in Appendix B and other supporting documentation is provided in Appendix C.

1.1 Hydrogeologic Setting

Hydrogeologic information was obtained from the Final Phase II Environmental Baseline Survey (EBS) Site Assessment Report prepared by BEM Systems, Inc. (BEM, 2013). Significant hydrogeologic units are present in the vicinity of PDX. These units include, in descending order, the Overbank Deposits, the Columbia Sand River Aquifer (CRSA), the Troutdale Gravel Aquifer (TGA), Confining Unit 1, the Troutdale Sandstone Aquifer, Confining Unit 2, and the Sand and Gravel Aquifer.

Several hydrogeologic units underlying PDX are part of a regional aquifer system that serves as the City of Portland's supplemental water supply.

The depth to groundwater in wells completed in the Overbank Deposits and the CRSA generally ranges from 2 to 10 feet below ground surface (bgs), depending on location, seasonal influences, and long-term precipitation trends. The inferred groundwater flow direction in the Overbank Deposits is predominantly toward the west and northwest. The groundwater flow direction in the CRSA, indicated by data collected prior to the Phase II Remedial Investigation (RI), was primarily toward the northwest. Water level data collected during a Phase II RI suggests that the groundwater flow direction in the CRSA fluctuates between northeast and south.

Further discussion of area wells is included in Section 3.3.1.1 of this report.

2.0 FIRE TRAINING AREAS

Based on this PA investigation, there is no evidence that an FTA is or was located within the footprint of the Base boundary. ANG Fire training is conducted in conjunction with Port firefighters on PDX property, and until 1979, fire training was conducted by the ANG on PDX property at the closed Environmental Restoration Program (ERP) Site 7 (CH2M Hill, 2006) located immediately east of the Base.

(This page intentionally left blank)

3.0 NON-FIRE TRAINING AREAS

Non-FTA Areas of Concern (AOCs) are sites where AFFF has been stored or released and may include crash sites, hangars, fuel spill areas, hazardous waste storage facilities, firefighting equipment testing areas, etc. The following section includes a description of any non-fire training AOCs identified during this PA effort including operational history, waste characteristics, and pathway evaluations, as applicable.

3.1 Description, Operational History, and Waste Characteristics

The following are the Non-FTA AOCs that were identified during this PA investigation. Appendix A includes photos of these areas from the August 2015 site visit, and Figure 2 depicts the areas.

3.1.1 Base Supply – Building 170

The Base Supply Building – Building 170 was built in 1990 and is located in the central portion of the Base. The building has stored AFFF for at least the last 10 years, but likely has stored AFFF since its first use on the Base. According to Base supply personnel, no AFFF has been spilled in the building. Currently, twenty-seven 55-gallon drums of AFFF manufactured by 3M and National are stored at this location.

3.1.2 New Fire Department – Building 180

The new Fire Department (FD) Building 180 was constructed in 2005. According to personnel that have worked at the Base FD since the late 1980s, the AFFF stored at this location is currently in Fire/Crash Response vehicles, including three crash trucks (two 25- gallon trucks and one 250-gallon truck), one fire engine (250 gallons), and one foam trailer (2,000 gallons). One former crash truck, awaiting disposal at the motor pool, contained 130 gallons. FD personnel indicated that there were minor spills which occurred during filling the vehicles over the years from on-site containers (now removed), and minor leaks from the equipment. Additionally, at least three occurrences of AFFF being discharged to the stormwater sewer system were documented in the Annual Storm Water Reports. These reports, as well as

schematics showing the locations of the storm water catch basins receiving the AFFF, are included in Appendix C-1.

3.1.3 Hangar 250

Hangar 250 was built in 1985. AFFF is stored in fire suppression equipment in the mechanical room of this hangar. According to the label, the tank has a design capacity of 200 gallons but the net contents are 55 gallons of AFFF. There have been minor leaks of AFFF in this room, with no reported inadvertent releases in the hangar. Currently, no AFFF is present in the hangar, although one empty 55-gallon barrel is currently present. No records of spills are reported to have occurred at this location.

3.1.4 Hangar 255

Hangar 255 was constructed in 1956. AFFF is stored in fire suppression equipment in the mechanical room of this hangar. The placard on the tank states that it contains 600 gallons of AFFF manufactured in 1994. There have been minor leaks of AFFF in this room, with an inadvertent release in the main hangar.

On October 19, 2005, Environmental Management (EM) personnel noticed foam on the pavement near Hangar 255 and questioned the local office personnel. The investigation indicated that the AFFF system in the hangar had been tested earlier that day as part of an annual testing program and 0.5 gallon of pure AFFF mixed with 49.5 gallons of water overflowed the system and was rinsed off the pavement into a storm drain located on the south side of Hangar 255 (see schematic in Appendix C-1). EM personnel reported the incident to the Oregon Department of Environmental Quality (ORDEQ) and further AFFF testing that day was suspended. EM personnel inspected the stormwater ditches and stormwater detention ponds to look for evidence of foam. On October 20, 2005, the ditches and ponds were again inspected and no foam was evident. A sample was collected at Outfall 10 and analyzed for biochemical oxygen demand 5 (BOD5). The actual BOD5 result was greater than 300 milligrams per liter (mg/l) since the high oxygen concentrations saturated the test and could not yield a true value. On October 21, 2005, the stormwater ditch feeding the north pond showed evidence of foam. Six aerators in the north pond and eight aerators in the south pond kicked up small patches of persistent foam covering an estimated area of 16 square feet. By the afternoon that day, the foam

had dissipated. A sample was again collected and analyzed for BOD5 which yielded a concentration of 10 mg/L. The problem was discussed with Civil Engineering (CE) management personnel. CE personnel redesigned the plumbing configuration to prevent future annual AFFF testing at Hangar 255 from discharging to the storm sewer system. Appendix C-1 contains the page from the Annual Storm water report detailing the release.

3.1.5 Old Fire Department and Swale – Building 290

Building 290 was built in 1986 and housed the old FD from approximately 1986 - 2005. According to personnel that have worked in this building since the late 1980s, AFFF was historically stored at this location in Fire/Crash Response vehicles. FD personnel indicated that there were minor spills which occurred during the filling of vehicles over the years from on-site containers (now removed), and minor leaks from the equipment. Additionally, personnel indicated at least one spill of AFFF of unknown quantity discharged to the drainage swale northwest of the building.

3.1.6 Hangar 310

Hangar 310 was built in 1988. AFFF is stored in fire suppression equipment in the mechanical room of this building. There are three tanks in the room, very similar in size to the tanks in Hangar 375, although there were no volumes listed on the tanks. It is presumed that two of the tanks contain 800 gallons and one contains 600 gallons. The date of manufacture listed on the tanks is 1987. There have been minor leaks of AFFF in the room, with an inadvertent release in the main hangar. It is likely that most of the inadvertent release of AFFF was hosed off into the floor drain within the hangar which is connected to the sanitary sewer system. Some of the AFFF would also likely have made its way onto the ramp to the north of Hangar 310, and then into the storm sewer system.

3.1.7 Hangar 380

Hangar 380 was built in 1986. AFFF was stored in fire suppression equipment in the mechanical room of this building. There currently are no tanks in the room. It is reported that the tanks were removed in 2005. Personnel interviewed did not know of any discharges in the room or in the main hangar.

3.1.8 Hangar 375

Hangar 375 was built in 1988. AFFF was stored in fire suppression equipment in the mechanical room of this building. There are three tanks in the room with no labels listing their volumes. It is presumed that two of the tanks contain 800 gallons and one contains 600 gallons. There have been minor leaks of AFFF in the room, with an inadvertent release in the main hangar. It is likely that most of the inadvertent release of AFFF was hosed off into the floor drain within the hangar which is connected to the sanitary sewer system. Some of the AFFF would also likely have made its way onto the ramp to the north of Hangar 375, and then into the storm sewer system.

3.1.9 POL Storage – Building 431

Petroleum, Oils and Lubricants (POL) are stored in Building 431 which was constructed in 1994. This building formerly contained the AFFF system tank that provided fire protection for the fuel tanks. No leaks or inadvertent discharges were reported and the system was removed in 2013.

3.1.10 Ponds/Stormwater Retention Basins

There are two man-made, shallow ponds located in the west central portion of the Base that receive 95% of the Base's stormwater discharge. These ponds are fed by ditches which converge just north of the ponds where the stormwater is discharged into the ponds through a pipe. All of the previously aforementioned releases to the storm sewer system eventually made their way to these two ponds. The ponds are located near the western boundary of the Base, as shown in Figure 2.

3.2 Pathway and Environmental Hazard Assessment

The following is a preliminary evaluation of the threats and targets associated with each potential exposure pathway. In their anionic forms, perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA) are water soluble and can migrate readily from soil to groundwater. The United States Environmental Protection Agency (USEPA) has not established Provisional Health Advisory Levels (PHALs) for PFOS and PFOA in soil (USEPA, 2014). The primary exposure pathway for PFOS and PFOA would be the ingestion of contaminated drinking water.

3.2.1 Groundwater

Groundwater at the Portland ANG Base is currently not being used. There is no evidence of PFCs in groundwater at the Base. However, based on historical practices, they may be present in the groundwater in the following areas:

- New Fire Department – Building 180
- Hangars 255, 310, and 375
- Old Fire Department – Building 290
- Ponds/stormwater retention basins

3.3.1.1 Water Wells

A review of the EDR Radius Map™ Report with Geocheck® dated July 21, 2015 shows 153 water wells within a one-mile radius of the Base (Appendix C-2) (EDR, 2015). One well is listed on the United States Geological Survey (USGS) database which usually lists monitoring or test wells. Other than a construction date of 1959, no additional relevant information was provided about this well. The remaining 152 water wells listed in the EDR Report are on the state's database. The majority of these wells appeared to be monitoring wells and none were listed as potable wells.

The City of Portland has a well field approximately 0.75 mile southeast of the Base which is used as a supplemental water supply for the City of Portland. The location of the well field is included in Appendix C-3. In addition, information provided from the 2006 EBS shows several additional water wells around the Base. Two water wells were identified in the EBS within a 1-mile radius of the property (EDR 2005). However, these wells are not listed as existing wells on the State of Oregon Water Resources Department, online Well Log Query (http://www.wrd.state.or.us). In addition, Roger Rein, the 142 FW Environmental Manager, provided a list of eight unregistered wells that are located between 0.75 and 1.25 miles from the base. These wells are included in a table presented in Appendix C-3. According to Mr. Rein, some of these wells are used for domestic consumption.

3.2.2 Soil

No documentation was available showing that soils at the Portland ANG Base have been tested for PFCs; therefore it is unknown whether PFCs are present in the soil. However based on historical practices, they may be present in the soil in the following areas:

- Hangars 255, 310, and 375
- Old Fire Department – Building 290

3.2.3 Sediment

No documentation was available showing that sediments at the Portland ANG Base have been tested for PFCs; therefore it is unknown whether PFCs are present in sediments. Based on historical practices, PFCs could be present in sediment at the Ponds/Stormwater Retention Basins that have received drainage from the following locations:

- New Fire Department – Building 180
- Hangars 255, 310, and 375
- Old Fire Department – Building 290

3.2.4 Surface Water

Surface water at the Base is dictated by the Base's man-made surface drainage system. Based on historical evidence, PFCs could be present in the surface water of the Ponds/Stormwater Retention Basins that have received drainage from the following locations:

- New Fire Department – Building 180
- Hangars 255, 310, and 375
- Old Fire Department – Building 290

Drainage patterns at the Base and its surrounding areas are included in Appendix C-4. A few potential environmentally sensitive areas around the Base are identified to be on the National Wetland Inventory according to the EDR Report (EDR, 2015), as shown in Appendix C-5.

(This page intentionally left blank)

4.0 FINDINGS AND CONCLUSIONS

Ten potential AOCs have been identified at the Base during this PA as summarized in Table 1. Of these ten sites, nine are recommended for further investigation to characterize potential PFC contamination.

Sampling of soil, groundwater, surface water, and sediments at these AOCs is recommended at a minimum to evaluate the potential migration of PFCs. In addition, verification of the structural integrity of the trench drains, sanitary sewer and stormwater sewer is also advised.

Table 1 summarizes the recommendation and rationale for each AOC identified at the Base.

Table 1: Preliminary Assessment Report Summary and Recommendations

No.	Potential AFFF PFC AOC	GPS Coordinates		Rationale	Recommendation
		Latitude	Longitude		
1	Base Supply – Building 170	45.577606°	-122.59358°	The station has stored AFFF at this location for at least the past ten years. According to Base personnel, no AFFF was spilled in the building.	NFA
2	New Fire Department – Building 180	45.578619°	-122.59530°	FD personnel indicated that there were minor spills which occurred during filling the vehicles over the years from on-site containers and minor leaks from the equipment. Additionally, at least three occurrences of AFFF being discharged to the stormwater sewer system were documented in the Annual Storm Water Reports.	Proceed to SI. Focus on groundwater.
3	Hangar 250	45.579040°	-122.58996°	Minor leaks of AFFF have occurred in the mechanical room. There are no records of inadvertent releases in the hangar; however, if releases did occur, they may have potentially impacted the adjacent ramp	Proceed to SI. Focus on soil and groundwater at the downgradient edges of the ramp based on surface drainage patterns.
4	Hangar 255	45.578432°	-122.59150°	Minor leaks of AFFF have occurred in the mechanical room, with one inadvertent release in the main hangar. It is likely that most of the inadvertent release of AFFF was hosed off into the trench drain that connects to the sanitary sewer systems, with some of the AFFF making its way onto the ramp, and then into the storm sewer system.	Proceed to SI. Focus on soil and groundwater at the downgradient edges of the ramp based on surface drainage patterns.

No.	Potential AFFF PFC AOC	GPS Coordinates		Rationale	Recommendation
		Latitude	Longitude		
5	Old Fire Department and Swale – Building 290	45.579859°	-122.59562°	FD personnel indicated that there were minor spills which occurred during filling the vehicles over the years from on-site containers and minor leaks from the equipment. Additionally, at least one occurrence of AFFF being discharged to the stormwater sewer system is documented in the Annual Storm Water Reports. Reports of AFFF making its way to the drainage swale have also been documented.	Proceed to SI. Focus on soil, sediment, surface water and groundwater.
6	Hangar 310	45.580564°	-122.59673°	Minor leaks of AFFF have occurred in the mechanical room, with an inadvertent release in the main hangar. It is likely that most of the inadvertent release of AFFF was hosed off into the trench drain that connects to the sanitary sewer systems, with some of the AFFF making its way onto the ramp, and then into the storm sewer system.	Proceed to SI. Focus on soil and groundwater at the downgradient edges of the ramp based on surface drainage patterns.
7	Hangar 380	45.581593°	-122.59977°	AFFF was stored in fire suppression equipment in the mechanical room of Hangar 380. The fire suppressions system tanks are no longer present and were reportedly removed in 2005. There were no known discharges in the room or in the main hangar; however, if releases did occur, they may have potentially impacted the adjacent ramp	Proceed to SI. Focus on soil and groundwater at the downgradient edges of the ramp based on surface drainage patterns.

Table 1: Preliminary Assessment Report Summary and Recommendations

No.	Potential AFFF PFC AOC	GPS Coordinates		Rationale	Recommendation
		Latitude	Longitude		
8	Hangar 375	45.582156°	-122.60075°	Minor leaks of AFFF have occurred in the mechanical room, with an inadvertent release in the main hangar. It is likely that most of the inadvertent release of AFFF was hosed off into the trench drain that connects to the sanitary sewer systems, with some of the AFFF making its way onto the ramp, and then into the storm sewer system.	Proceed to SI. Focus on soil and groundwater at the downgradient edges of the ramp based on surface drainage patterns.
9	POL Storage – Building 431	45.578289°	-122.59729°	This building formerly contained the AFFF system tank that provided fire protection for the fuel tanks.	Proceed to SI. Focus on soil and groundwater.
10	Ponds/storm water retention basins	45.579761°	-122.60219°	These two ponds receive 95% of the Base's stormwater discharges. All of the previously aforementioned releases to the stormwater system eventually made their way to these two ponds.	Proceed to SI. Focus on sediment, surface water and groundwater.

AFFF – Aqueous Film Forming Foam
PFC – Perfluorinated Compound
AOC – Area of Concern
GPS – Global Positioning Satellite
NFA – No Further Action
FD – Fire Department
SI – Site Investigation
POL – Petroleum, Oils and Lubricants

INTERVIEW QUESTIONS AND RECORDS OF COMMUNICATION

142nd FW Portland, OR
see interview
26 Aug 2015
0900 HRS

see sign in sheet attendees for this interview

Interview Questions regarding AFFF use
(At Present and back to 1970)

all had AFFF exposure

250
255 – has AFFF late 70's, early 80's
310
380
375 POL

180 – New FD – Formerly stored
(290 OLD FD had AFFF)

1. When did AFFF first start being used on this installation?

FD – 20 some years
Mostly 6%

AFFF was on base in 1988 when Roger arrived.

2. What are the years of active use for each Fire Training Area (FTA), Aircraft Hangar, Fire Department, other places AFFF may have been used (collectively Potential Areas of Concern (PAOC)?

No FTA on base – on Port of Portland property

3. What type of AFFF is used or has been used on this installation (i.e. 3%, 6%, High Expansion Foam)?

– some stored in Bldg 170

Mainly 6%
some 3%

They have HEF – but are not concerned

4. ~~What~~ manufacturer's AFFF products are used or were used on this installation (i.e. 3M, Ansul, Chemguard, etc.)?

currently stored @ 170

5. Did you ever dispose of old bulk AFFF, if so, when and where?

Yes, Roger go through DLA. (A) ✓

6. Is the AFFF stored as a mixed solution (3% or 6%) or do you formulate the AFFF on the installation?

see above

7. If AFFF is formulated on base, where is the solution mixed, contained, transferred, etc.?

NO

8. Are your automated fire suppression systems currently charged with AFFF or have they been retrofitted for use of high expansion foam?

250
255
310
} currently

380 used to
375 may have AFFF

9. If retrofitted, when was that done?

- new MEF systems only
- no retrofitting

10. Do you have an inventory of the amount of AFFF stored on the installation, now and in the past, or present in automated fire suppression systems? Were retention ponds built to store discharged AFFF? Was the AFFF trickled to the sanitary sewer or left in the pond to infiltrate?

Bldg 170 - FD - only on trucks

NO

Testing of systems - Backentank for sanitary

11. Provide a list of vehicles that carried AFFF, now and in the past, and where are/were they located? Any vehicles have a history of leaking AFFF?

yes, minimal amount

3 crash trucks — 25 gal
" " — 250 gal
1 engine - 50 gal
1 Foam trailer - 2000 gal

(former) P19 - 136 gal
P19 - 250 (now)

former P19 old crash POL in carries 130

12. How much AFFF (gallons) is/was carried/stored in the specified vehicles?

see above

13. Do you ever dispose of unused AFFF? If so, how and where?

(A) Yes, Goes through Roger

14. Has unused AFFF ever been disposed of in the past? If so, how and where?

(A) Yes, check w/ Roger

15. Do you/did you test the vehicles spray patterns to make sure equipment is working properly?

Yes, but on Post Property

16. How often are/were these spray tests performed and can you provide the locations of these tests, now and in the past?

annual

17. Can you describe the procedure on how vehicles and systems are/were supplied with AFFF?

pouring or pump from Foam trailer

18. Can you provide the procedures on how these vehicles are/were cleaned/decontaminated and where vehicle cleaning is performed currently as well as performed in the past?

auto soap - washed inside.

19. Is/was there a specified area on the installation where vehicles are filled with AFFF and does this area have secondary containment in case of spills?

~~No~~ ~~to~~ Primarily in Fire Station

20. When a release of AFFF occurs during a fire training exercise, now and in the past, how is the AFFF cleaned and disposed of?

at Port

✓(A) - some spilled @ Bldg 290 in swale.

21. How many FTAs are/were on this installation and where are they?

None

22. How many FTAs are active and inactive?

None

23. What types of fuels/flammables were used at the FTAs?

N/A

24. For inactive FTAs, when was the last time that fire training using AFFF was conducted at them? Find out ahead of time in Admin Record for former FTAs.

N/A

25. What are/were the non-FTA locations where PFCs or AFFF release systems are installed (i.e. Hangars, Wastewater Treatment Plants, Fire Stations, etc.)? Where are/were these locations (Building numbers)?

NO

See previous

26. Do you have a list (Building names and numbers, current and demolished) where the fire suppression systems either currently contain or have contained AFFF?

See previous

27. Do you have records of fuel spill logs and emergency response logs? Knowledge of aircraft mishaps/crashes?

Do not use AFFF on Fuel spills.

Used on ag equip, small issues east apron

28. Do you have recollection or records of AFFF being used as a precaution in response to fuel releases to prevent fires?

No.

29. Do you have recollection or records of historical emergency response sites (i.e. crash sites and fires) where AFFF was used?

On Port Property

30. Do you have recollection or record of emergency runway landings where foam might have been used as a precaution?

No

31. If not written records or incomplete written records, do you have anecdotal/verbal information and locations of spills or other emergency response incidents where AFFF was used?

F

No.

√ w/ Scott.

32. What is the typical procedure for removing dispensed AFFF from an area where it has been used? - First try to contain it. - Flush into drains - sanitary

33. Can you provide any other locations where AFFF has been stored, released, or used (i.e. hangars, buildings, fire stations, firefighting equipment testing and maintenance areas, emergency response sites, storm water/surface water, waste water treatment plants, and AFFF ponds)? 180
290
170
plus hangar

34. Do you have or did you have a chrome plating shop on base? If no, skip to Question #38.

No

35. What were/are the years of operation of that chrome plating shop?

N/A

36. Do you know whether the shop has/had a foam blanket mist suppression system or used a fume hood for emissions control? N/A

37. If foam blanket mist suppression was used, where was the foam stored, mixed, applied, etc.?

N/A

38. Is there anyone else or other base organization personnel that you would recommend we interview? Name, organization, position, phone number, e-mail.

(A) Jw/him tomorrow → (A) John LeCarno - alarm technician

39. Was it common practice to wash away fuel spills with AFFF?

NO

40. Identify drainage patterns around flightline/ramp area. Point source discharge is likely AFFF Area of Concern (AOC).

Meeting Notes

Thomas Albright, Base Plumber (at base, since 1999)
- AFFF still in Bldg 375 (going to Port @ end of fiscal year)
- All 300 Bldgs are former AFRC, left in 2008. Flying presence

- Bldg 170 - storage of AFFF
- Bldg 250 - currently has AFFF
- " 255 - has AFFF
- " 290 - had AFFF
- " 310 - has AFFF - weapons release + munitions trng
- " 380 - former AFRC - had AFFF in 11 2005
- " 375 - " " - has AFFF in system

142nd FW
Portland, OR

26 Aug 2015

Aviva Johnston - @ base since 2001
Nat. Resource ~~Ex~~ Specialist II

- ~~Extir~~ All sanitary lines (Mains) were replaced in 2013 south of ~~2013~~ O Connor (those which were in bad shape)

- Northern Sanitary lines were inspected via camera and were found to be in Good condition. This is where AFFF discharges took (hangar, FD, etc.)

No Sam

- Aviva wrote reports on Annual SW that detail AFFF discharge incidents. - we have copies

142nd FW
Portland, Oregon 27 Aug 2015

John LeCarno, Electrician, been @ base 23/24 years.

John took me around to view AFFF sys in different Hangar

✓ 250 Hangars - AFFF - tank present - net contents 55 gals / Marked 200 gal design capacity
minor leaks in room, no inadvertant releases to John's knowledge

✓ 255 Hangar - AFFF present, 600 gallons on placard on tank
✱ hanger had inadvertant release onto ramp tank instrd 1994, minor leaks in rooms

✓ 310 Hangar - AFFF still present, minor leaks in room, 3 tanks, 1 cover, 2 fuel volume
(similar to 375 ~~[illegible]~~ - no markings)
✱ Hangar had inadvertant release, went onto ramp, tank instr 1987

✓ 380 Hangar - AFFF tanks gone, No recollection of discharge

✓ 375 Hangar (to be turned over to Port in Dec 2015)
3 AFFF tanks, 800, 600, 800 gallon tanks
1 1 |
1987, 1986 2005
✱ Inadvertant release from hangar,
minor leaks in room

275 - has HEF, never had AFFF

142ND FW 8/27/2015

- Portland, OR -

(Discussion w/ Roger Rein)

Testing of AFFF systems was done w/ water (sometimes collected in a Baker tank) & often discharged into sanitary sewer

AFFF is profile #130

130B is not AFFF

Records of AFFF leaving base

- shipped out to DRMO (or DLA)
- Roger sent email to me w/ records (2008 to present)
  - had electronic records back to 2008
  - prior to 2008, hardcopies are available
  - Roger arrived @ base in 1988

- went through archived paper files, found several examples of AFFF Disposal through DRMO.

APPENDIX C

SUPPORTING DOCUMENTATION

APPENDIX C-1

STORMWATER REPORTS

DISCUSSION OF SPRING BENCHMARK EXCEEDENCES AND SUSPECTED CAUSES

Spring stormwater samples showed exceedances at Outfall 008. Phosphorus results showed levels at 0.40 mg/L and oil and grease results showed 12 mg/L. This outfall contains stormwater that is co-mingled the Port of Portland stormwater. Prior to the change in the drainage infrastructure, stormwater from a corner the runway owned by Port of Portland, flowed over a grassy area. Stormwater from the tarmac now flows into a catch basin that is directly piped into PANG's sampling basin. It is suspected that oil and grease from taxiing aircraft impacted stormwater samples. A long-term phosphorus investigation is currently being conducted and a report will be forwarded to DEQ upon completion. Anticipated completion date is September 2005.

The EM office is aware that samples from Outfall 008 are not exclusively representative of PANG's stormwater. Future plans to increase sampling efforts by retrofitting the Port of Portland's drainage pipeline with a sampling basin will allow the Port's stormwater impacts to be subtracted out from the co-mingled stormwater samples.

UNPERMITTED DISCHARGES TO STORMWATER

On September 20, 2004, while conducting field work, Environmental Management personnel noticed the far west end of the Guard apron undergoing reconditioning of the pavement joints. This operation did not appear to be significant at the time. On October 28, 2004 at 11:00 Environmental Management personnel noticed that joint removal operations on the Guard apron had generated fines and that equipment had spread the fines over approximately 3 acres of tarmac. DEQ was notified of the incident and the following week custom "dead end flow" stormwater traps were installed in the catch basins draining to Outfall 050. On November 18, 2004 six inches of standing water interfered with flight line operations prevention aircraft from flying. Traps were removed and contents disposed. November 24, 2004 new traps installed to collect residual fines on the apron. On December 7, 2004 six inches of standing water interfered with flight line operations preventing aircraft from flying. Storm drain traps were removed and contents disposed. Civil Engineering personnel, managers of base construction projects, were once again reminded of NPDES II construction requirements for disturbing an acre or more of surface areas.

In December 2004 shop personnel in Building 160 squeegied water from a floor into a trench drain located inside the building. This trench drain was identified during an illicit discharge survey conducted last summer as being connected to the stormwater system. On June 13, 2005 the trench drain outlet was plugged with concrete to prevent discharges to storm.

April 6, 2005 at about 2:30 PM, EM personnel noticed a contracted construction worker using a hose to discharge very brown water, flushing from a newly installed fire suppression system in the new Fire Station, into a storm drain. The worker was told to stop the discharge immediately. The Army Corps of Engineer's point of contact was informed again that construction related discharges are not allowed to storm. A

Bldg 180

construction contractor training program for base stormwater policies was implemented as a BMP to prevent reoccurrence.

In mid April, 2005 EM personnel noticed a small pile of detergent flakes and suds in a parking lot indicating that vehicle washing was recently performed. The Environmental Manager informed the nearby shop in Building 165 that washing vehicles in the parking lot violates the stormwater permit and in the future to wash vehicles at a wash rack that is plumbed to an oil water separator.

On April 22, 2005 at 10:30 EM personnel noticed a contractor had connected dewatering discharge to a stormwater drain. EM personnel stopped the discharge and dewatering discharge was later connected to sewer. Dewatering to storm water had begun on April 18, 2005 at 15:10.

On April 26, 2005 at approximately 13:00 EM personnel and contractors noticed strong fuel vapors coming from a stormwater ditch located next to the POL compound. A large sheen was observed. The base Environmental Manager contacted Dan Hafly at DEQ who is provided clean-up oversight. A sample of sheened water was collected at Outfall 010 on May 6, 2005. Analysis showed that the concentrations of gasoline, diesel, and heavy oil hydrocarbons were less than 0.250 mg/L, 0.630 mg/L, and 0.630 mg/L respectively. The cumulative concentrations were below the 10.0 mg/L benchmark for oil and grease.

On May 3, 2005 at 8:30 EM personnel were informed of an improvised wash area over a storm drain located outside of CE shops. The managers of the CE shops were notified via email that rinsing Roads & Ground equipment at this wash area violated the stormwater permit and that all washing or rinsing activities must be done only at the approved wash areas on base.

On May 3, 2005 at 3:00 EM personnel were informed of rinsing hydraulic fluid from hard to reach spaces inside of aircraft. Rinsing operations apparently were performed on the Guard apron approximately two to three times per month. On May 19, 2005 EM notified the shop in writing to move rinsing operations inside a hangar where rinse water will be directed to an oil / water separator for pre-treatment and then discharged into the sanitary sewer system. The Environmental Manager also spoke with the shop manager to emphasis the importance of complying with the stormwater permit regulations.

On May 12, 2005 EM personnel witnessed two janitorial contractors pour a mop bucket full of soapy water into a storm drain. EM personnel directed the janitors to pour all buckets of water down drains located inside of buildings. Janitors stated they were unaware of the policy and in the future would comply. Interviews with other contracted janitors on base indicated additional discharges of mop water to stormwater drains due to logistic problems with sanitary sewer drains. EM requested Civil Engineering Dept, the janitorial contract managers, to address the logistical problems and base stormwater policies in the base janitorial contract.

DISCUSSION OF SPRING BENCHMARK EXCEEDENCES AND SUSPECTED CAUSES

There were no exceedances of benchmarks for the Spring sampling event.

The EM office is aware that samples from Outfall 008 are not exclusively representative of PANG's stormwater. Future plans to increase sampling efforts by retrofitting the Port of Portland's drainage pipeline with a sampling basin will allow representative sampling.

UNPERMITTED DISCHARGES TO STORMWATER

On August 23, 2005 personnel from Base Environmental noticed interior and exterior vehicle washing of a sweeper truck at a location near Outfall 10. The Civil Engineering (CE) department managers were notified that this operation violated the base wash water permit and that vehicle wash water needed to discharge to sewer. Further investigations indicated that sweeper truck washings have occurred near Outfall 10 for the past 30 years. As of September 7, 2005 CE implemented a wash rack plumbed to sanitary sewer to accommodate all discharges from the sweeper trucks including stormwater and have directed operators to wash the sweeper trucks at this designated wash rack.

On October 12, 2005 approximately 100 gallons of co-mingled rain water and ground water from two vaults were discharged by CE personnel to stormwater from 7:30 to 8:45 A.M. CE personnel were reminded that dewatering activities must be discharged to sanitary sewer.

On October 19, 2005 Environmental Management personnel noticed foam on the pavement near B-255 and questioned the local office personnel. The investigation indicated that the Aqueous Film forming Foam (AFFF) system in the building had been tested earlier that day as part of an annual testing program and 0.5 gallons of pure AFFF mixed with 49.5 gallons of water overflowed the system and was rinsed off the pavement into a storm drain located on the south side of B-255. Environmental Management personnel reported the incident to DEQ and further AFFF testing that day was suspended. The problem was discussed with CE management personnel. CE personnel redesigned the plumbing reconfiguration to prevent future annual AFFF system's testing at B-255 from discharging to storm. Environmental Management personnel walked the stormwater ditches and stormwater detention ponds looking for evidence of foam. On October 20th the ditches and ponds were again inspected and no foam was evident. A sample was collected at Outfall 10 and analyzed for BOD5. The actual BOD5 result was greater than 300 mg/L since the high BOD saturated the test and could not yield a true value. On October 21 the stormwater ditch feeding the north pond showed evidence of foam. Six aerators in the north pond and eight aerators in the south pond kicked up small patches of persistent foam covering an estimated area of 16 square feet. By the afternoon that day the foam dissipated. Again a sample was collected and analyzed. Results showed BOD5 at 10 mg/L.

OTHER NON-COMPLIANCE ISSUES

Bldg 180

On September 8, 2006 an AFFF spill occurred near the Fire Station. Fire Department personnel washed the spill down a nearby catch basin and then called the Environmental Manager. Since the catch basin was deep and fairly dry from lack of summer rains, the basin contained the spill completely. The spill/wash water was pumped out of the catch basin and containerized. FD personnel used a large roller mop to collect the remaining pooled AFFF from the pavement. The Environmental Manager reiterated to the Fire Department not to wash spills into storm drains.

On April 5, 2007 and April 12, 2007 personnel from Base Environmental witnessed a contracted janitor dump mop water down a storm drain. On May 9, 2007 the Environmental Manager received notice from an administrative employee at Portland Rehab and agreed that janitorial employees will comply with Stormwater permit regulations. The administrative employee affirmed that rehab employees have been directed to pour mop water down sanitary sewer lines instead of stormwater drains.

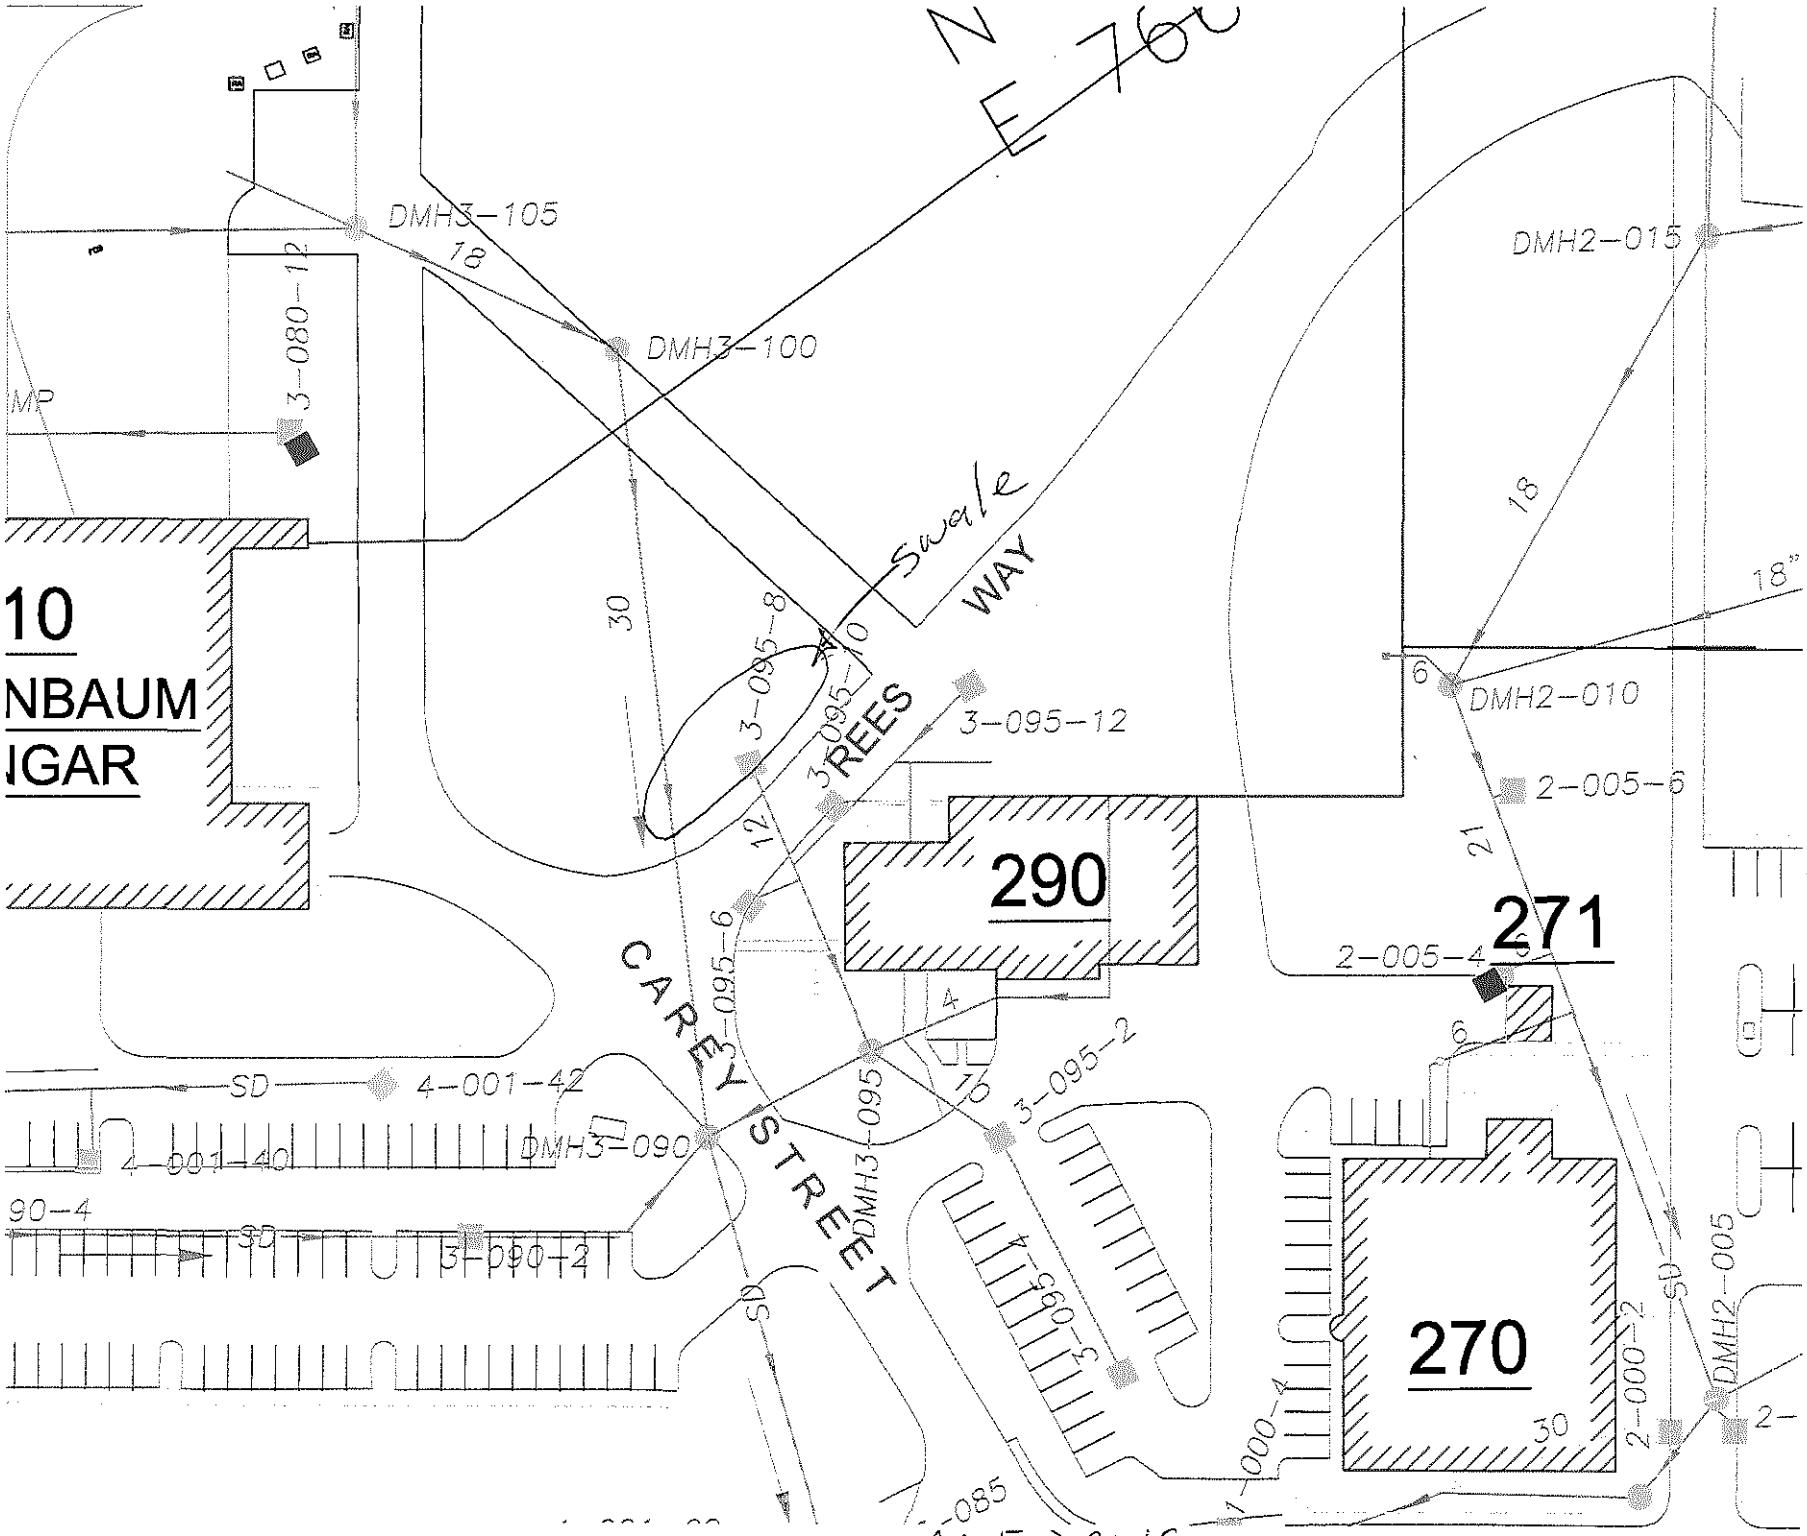
Schedule A, Item 3(c)(iv) requires mandatory stormwater training within 30 days of hire and annually thereafter. Annual mandatory stormwater training in a PowerPoint format was made available for base personnel at the Fire Station where a training tracking system was already in place for spill awareness and spill response. As of June 2007 the Deputy Fire Chief was not aware of any stormwater or spill training events for the period from July 1, 2006 through June 2007. The mandatory annual training requirement was discussed throughout quarterly meetings of the Environmental Protection Committee. The Base Commander is currently in the process of routing a letter to the Base Department Chiefs for recruiting training support. A compliance date with this requirement has yet to be determined.

Schedule A, Item 3(c)(i)(2) requires that oil water separators, booms, skimmers or other methods must be employed to eliminate or minimize oil and grease contamination of stormwater discharges. September 2006 the Environmental Manager submitted a work request repair the skimmer at the north pond that receives approximately 95 percent of the base stormwater. The repair is still pending. A compliance date with this requirement has yet to be determined.

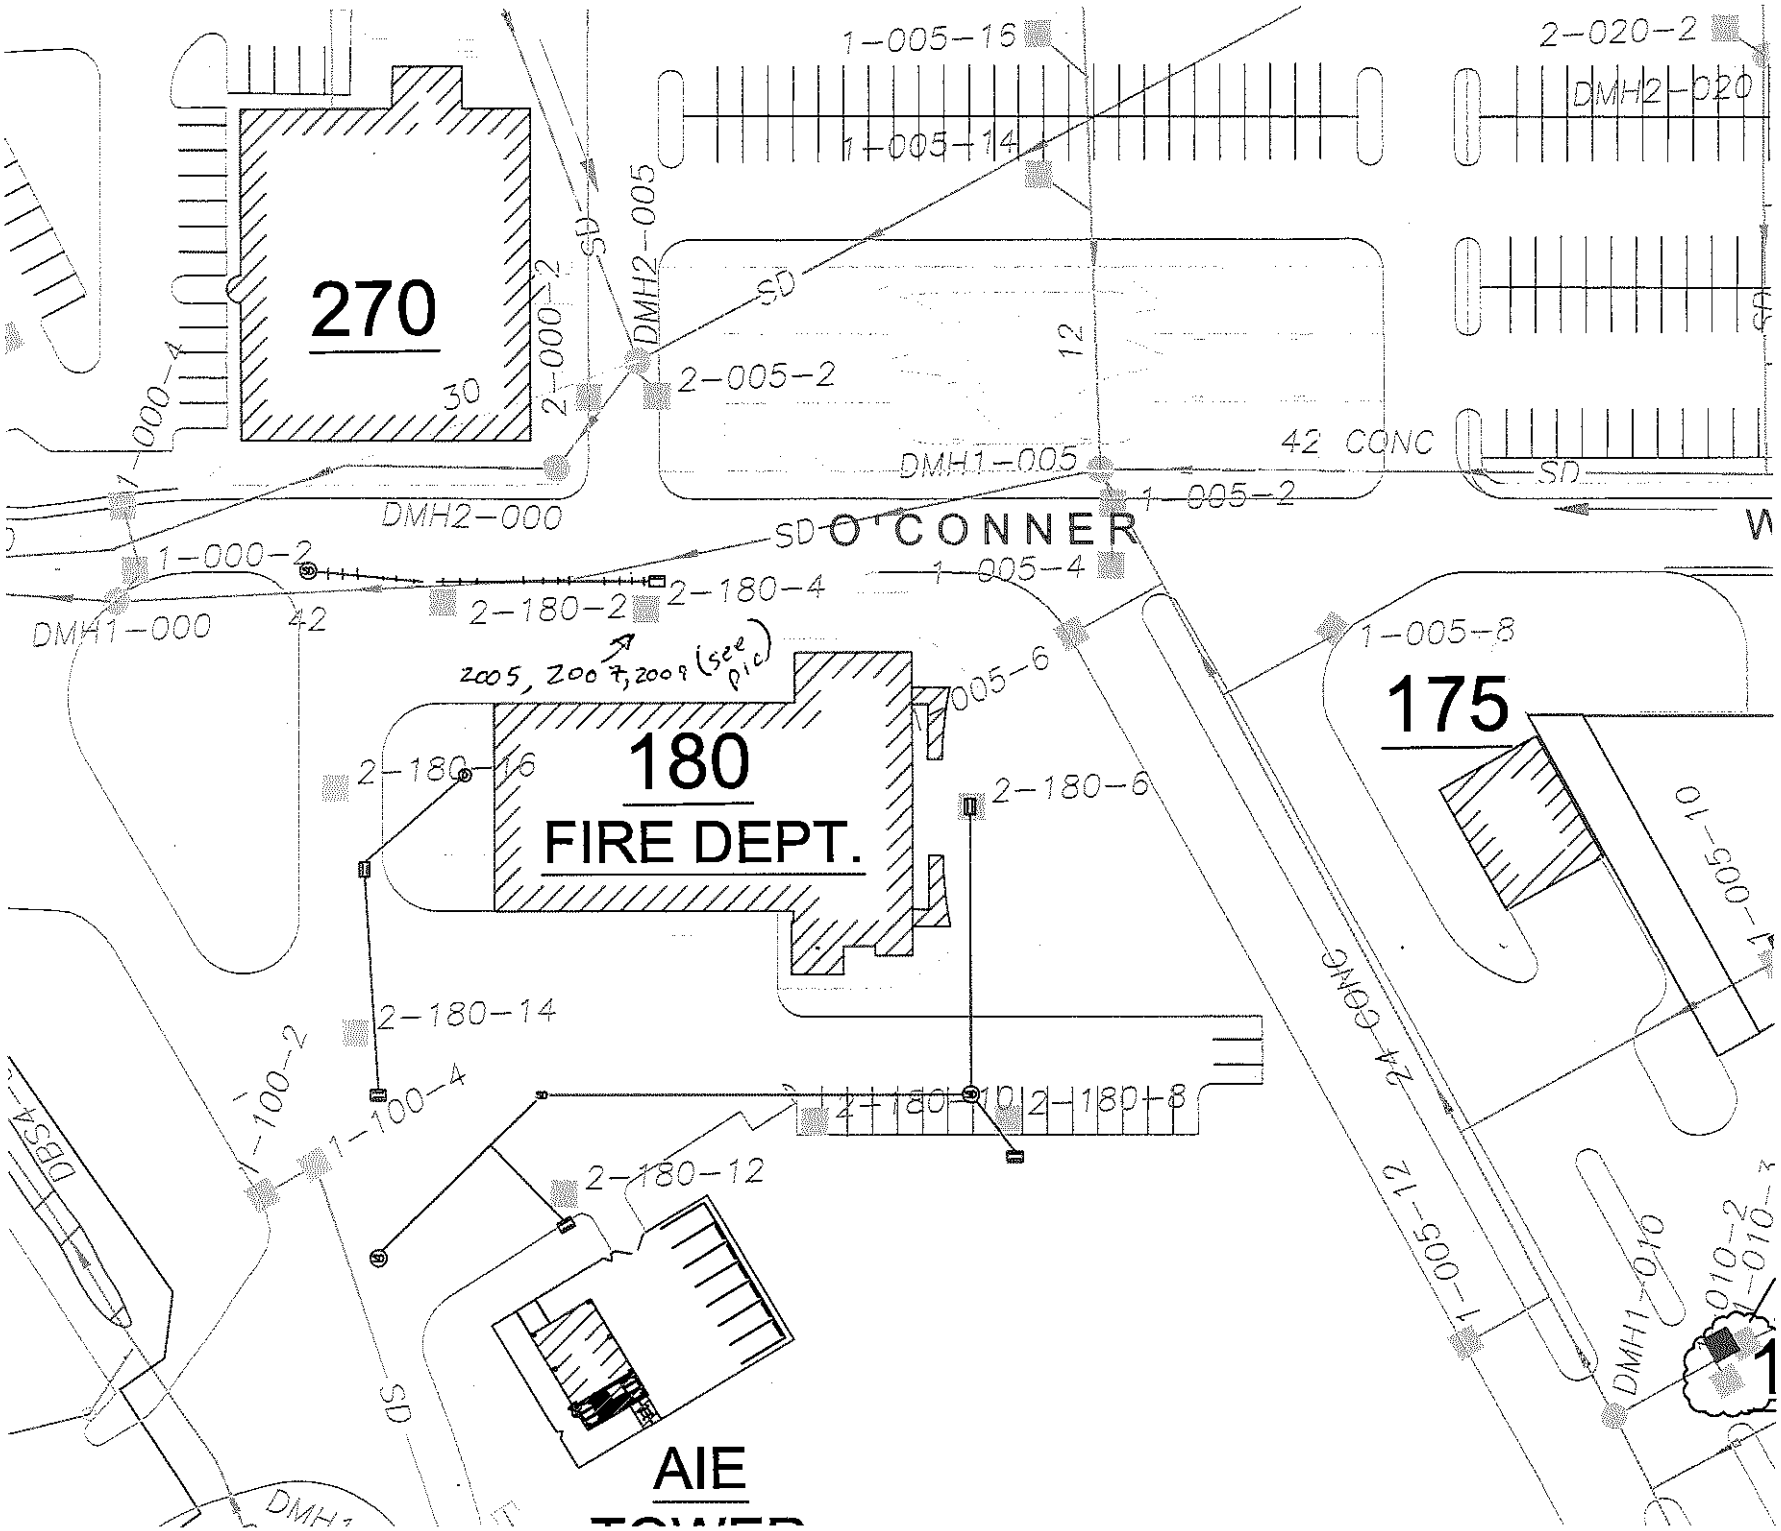
Phase II of an Illicit Discharge survey was conducted in the fall of 2006. The survey revealed a trench drain inside Building 275 discharged to the storm water system. September 2006 the Environmental Manager submitted a work request to plug the pipe inlet to prevent illicit discharges. Records show the repair was completed October 2006.

Phase II of an Illicit Discharge survey was conducted in the fall of 2006. The survey confirmed an abandoned oil water separator in Building 188 discharged to the storm water system. A record search showed that no work requests after September of 2006 were submitted to plug the floor drain or remove the oil water separator or check for possible soil contamination. Work request orders were submitted June 26, 2007 to plug

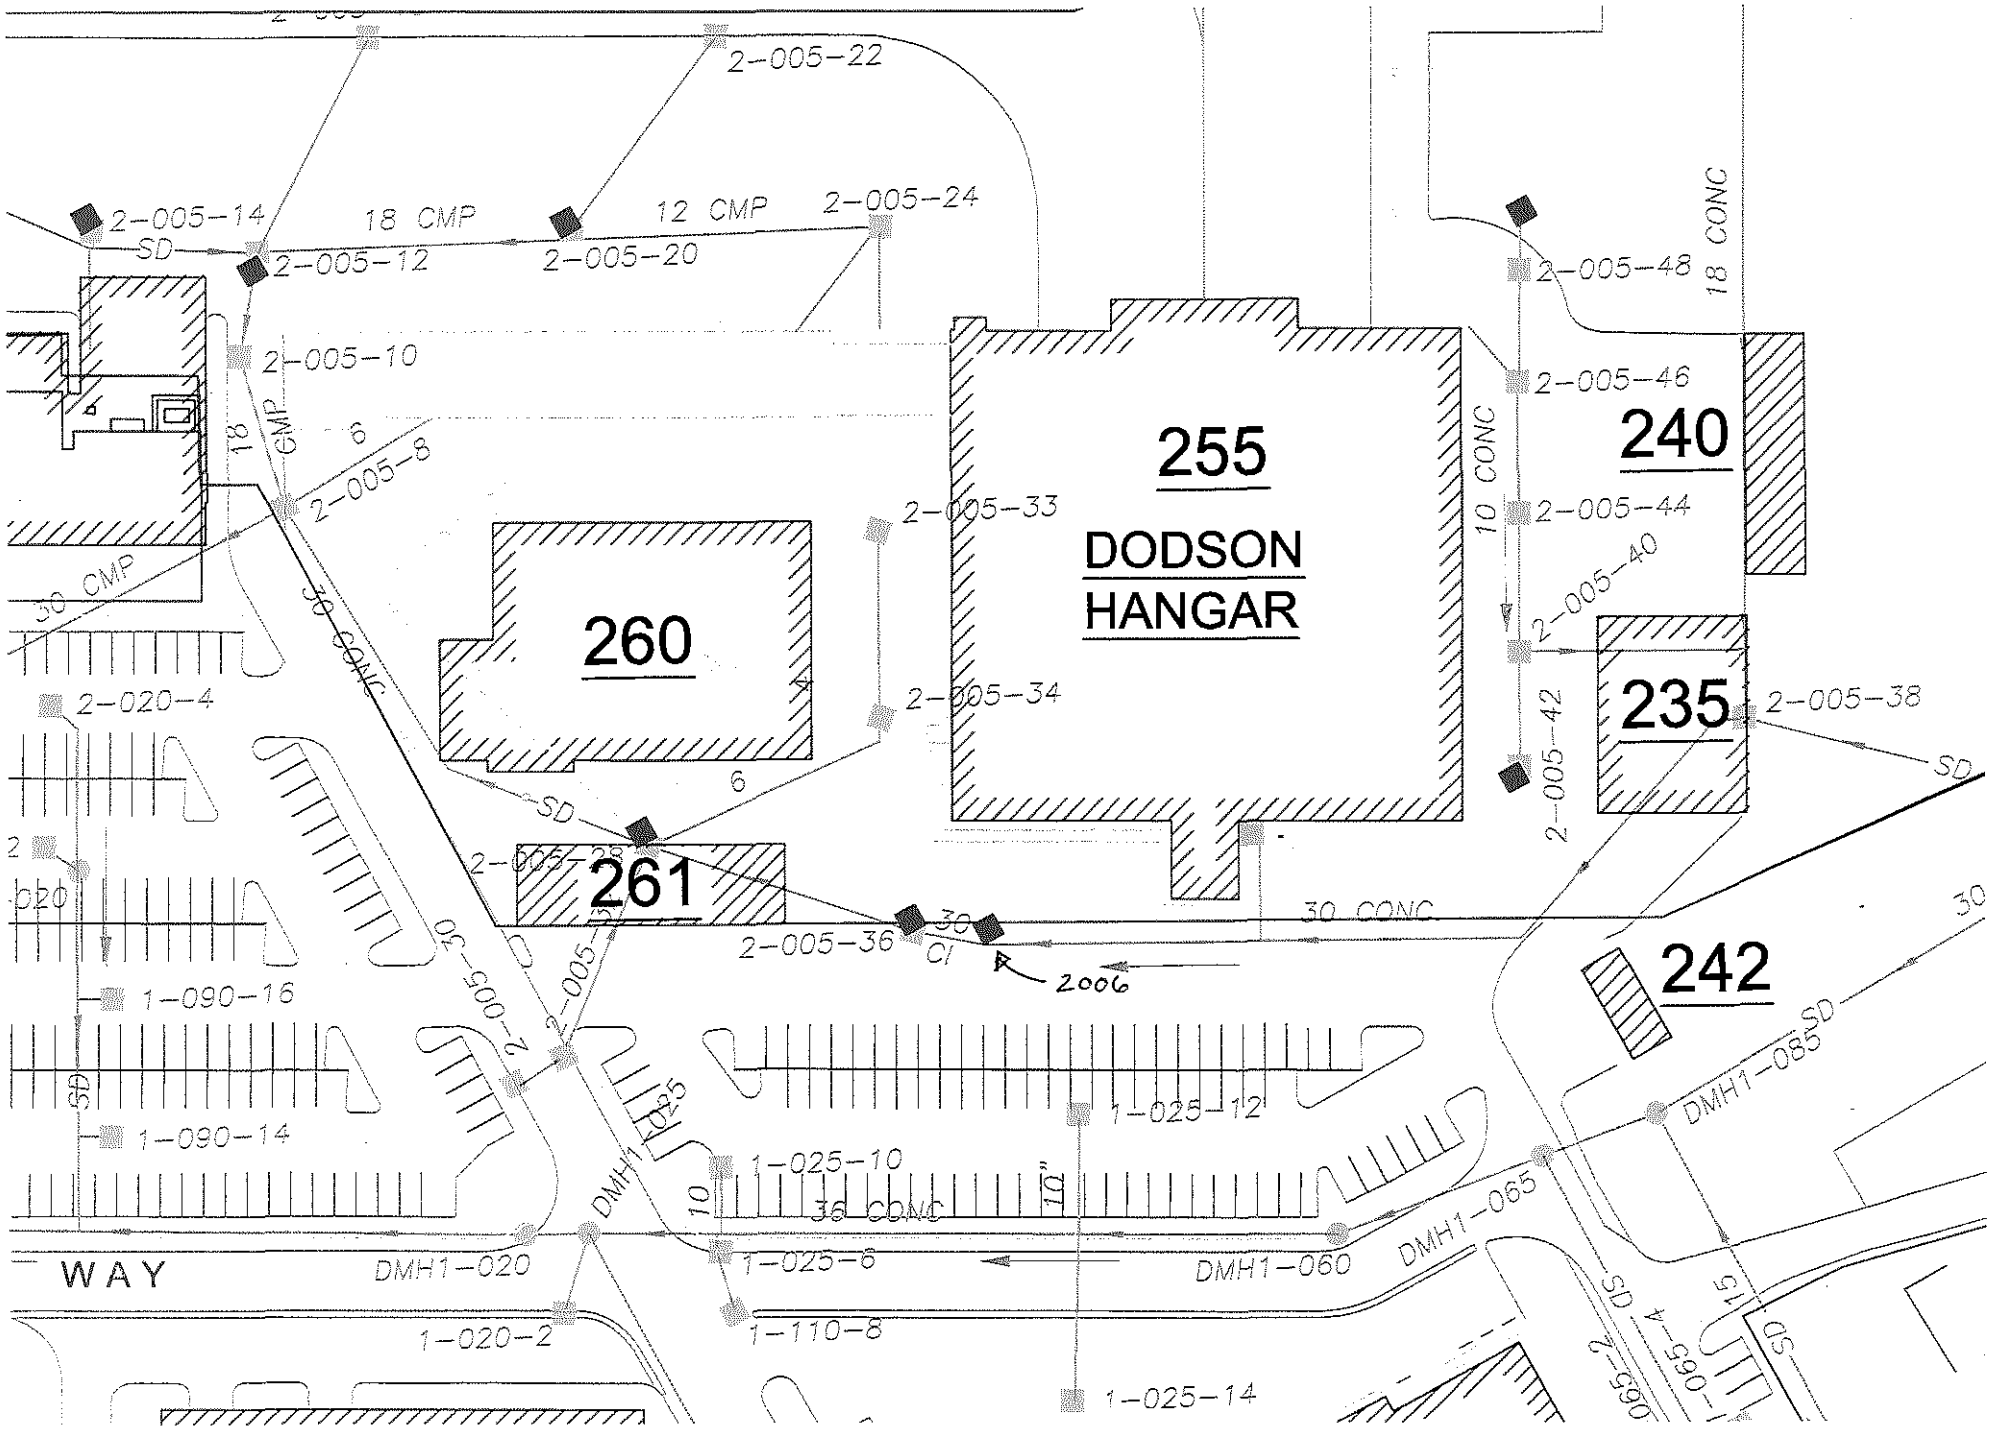
OTHER NON-COMPLIANCE ISSUES



On July 15, 2008 environmental personnel noticed a Blue Bird Bus being washed at the base vehicle wash rack. The overspray and spray off the large vehicle exceed the catchment area on all four sides. The cause was an undersized wash rack that causes overspray and ricochet spray to reach beyond the sloped catchment pad. Environmental personnel again alerted the Environmental Manager of the problem. During the 2007-2008 period of stormwater compliance reporting, the environmental manager scheduled an annual Environmental Management System (EMS) meeting to discuss with cross sectional team members how to best resolve this issue through a base work order. The EMS meeting on June 5, 2008 resulted in no recommendations or suggestions for a possible solution. Then the Environmental Protection Committee met on June 10th 2008 at which time the Wing Commander suggested to the Environmental Manager to request funding from Guard Headquarters for wash rack modification modify to meet compliance requirements. As of July 2009 the base commander has decided to enclose an unused outdoor wash rack at building 160 and remove the existing wash rack at building 435 from service. This project is being considered for FY 2009 funding. If this project is funded in FY 2009, it could be completed by 1 JUN 2010.



-Bldg 180



On August 7, 2008 at 11:00, Fire Department personnel was rinsing a transfer hose to removed trace product after using the hose to transfer Aqueous Film Forming Foam (AFFF) from a new mobile AFFF storage unit into a fire truck. After making the proper hose connections, the operator pointed the hose end into the indoor trench drain and opened the water supply. Unbeknownst to the operator, the rinse water supply line was pressurized causing the transfer hose to jump four feet over the trench drain located inside the building sending foam product (trace AFFF mixed with rinse water) into the driveway outside. The operator then tried to rinse the foam in the driveway back uphill into the trench drain but succeeded in creating more foam and a stream of water that sent everything into the nearest stormwater drain. It is estimated that ½ - 1 cup of pure AFFF was irretrievably discharged into the stormwater system. In the future, when AFFF transfer hose requires rinsing, the Fire Department plans to use the water source supplied from a fire truck (easier to control) instead of the plumbed high pressure water lines located above the work bays.

On September 2, 2008 at 11:20 environmental personnel notified the Environmental Manager that wet pavement from the bay driveway to the nearby storm drains at B-365 and the outdoor hose connection next to the buildings driveway indicate the tenants in B-365 had performed washing operations not in-compliance with the wash or storm permit. The EM called the building supervisor and reiterated that washing of any item is to be performed at the wash rack located on the other side of building and not in the bay door driveway and that this was already a repeat non-compliance discharge.

On September 3, 2008 at 11:30 environmental personnel alerted the Environmental Manager of a continuous discharge to the storm system from a cooling system located at B-155. A hose had been set up to spray water over an outdoor cooling system to increase efficiency. The continuous runoff drained to a catch basin. The Environmental Manager

EDR ONE-MILE RADIUS WATER WELLS MAP

GEOCHECK® - PHYSICAL SETTING SOURCE SUMMARY

LOCAL / REGIONAL WATER AGENCY RECORDS

EDR Local/Regional Water Agency records provide water well information to assist the environmental professional in assessing sources that may impact ground water flow direction, and in forming an opinion about the impact of contaminant migration on nearby drinking water wells.

WELL SEARCH DISTANCE INFORMATION

DATABASE	SEARCH DISTANCE (miles)

property (EDR 2005), and are listed in Table 3-4 (Wells 1 and 2). However, these wells are not listed as existing wells on the State of Oregon Water Resources Department, online Well Log Query (http://www.wrd.state.or.us). In addition, Roger Rein, the 142 FW Environmental Manager, provided a list of unregistered wells that are located around the base. These wells are also listed on Table 3-4. Some of these wells are used for domestic consumption (Roger Rein, personal Communication).

The western edge of Columbia South Shore Well Field is located approximately 0.75-mile from the Portland ANGB as shown in Figure 1-2. This well field is used as a supplemental water supply for the City of Portland (AFRC 2002).

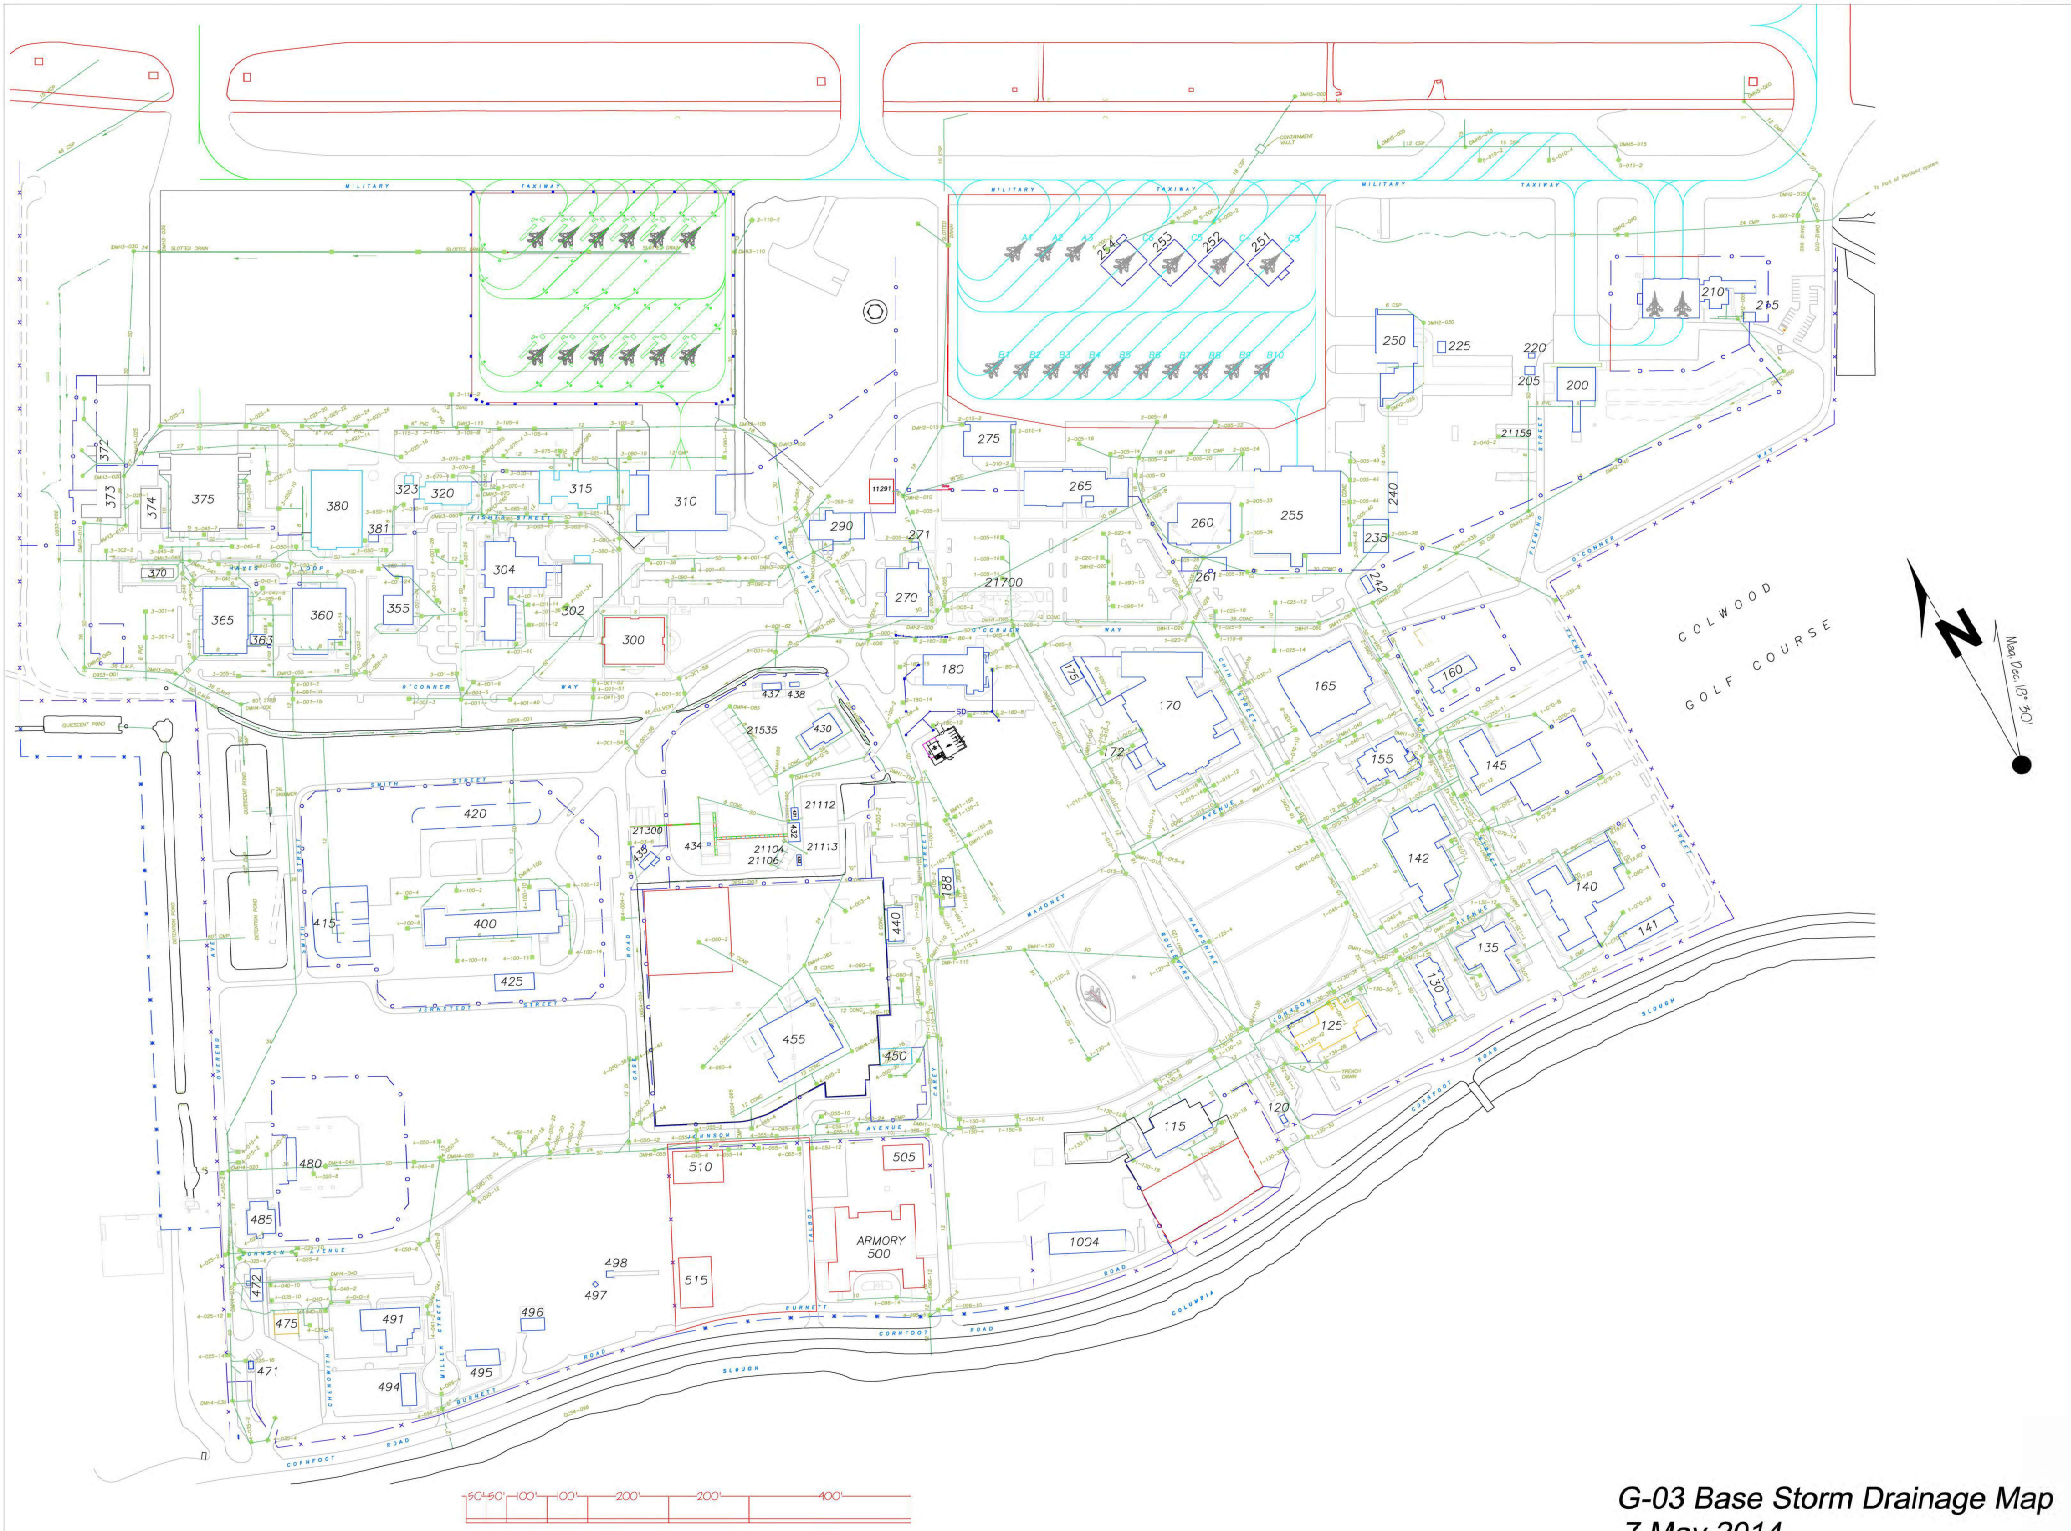

Table 3-4. Nearby Wells
Portland Air National Guard Base, Portland, Oregon

Well Number/Well Address	Distance and Direction	Potentiometric Location	Depth of Well	Water Uses

Executive Summary

At the request of the Port of Portland (Port), Apex Companies, LLC (Apex) prepared this Original and Former Fire Training Facilities Investigation Results Report (the Report) that presents the results for collection and chemical analysis of soil, groundwater, stormwater, surface water, and sediment samples located in the vicinity of, or potentially impacted by, the Original and Former fire training facilities (Original and Former Facilities; the Site) at Portland International Airport (PDX; Figures 1 and 2). Investigation activities are being conducted with oversight from the Oregon Department of Environmental Quality (DEQ) in accordance with the Voluntary Cleanup Agreement (VCP) between the DEQ and the Port of Portland (Port) for ECSI No. 3324, dated February 8, 2017. The purpose of the investigation was to assess and delineate impacts associated with fire training activities conducted at the Original and Former Facilities. This investigation was conducted in accordance with the Reconnaissance Well Sampling Work Plan dated April 13, 2017, Investigation Work Plan dated August 29, 2017, and Investigation Work Plan Amendment dated September 19, 2017.

The Original and Former Facilities are located in the northwest portion of PDX and were actively used for aviation firefighting drills since 1963. The Current Facility, which is lined to reduce the potential for introduction of chemicals to the subsurface, is located adjacent to the Former Facility and has been in use since 1989 (Figure 2). From 1988 through 2007, site characterization, subsurface investigations, and groundwater monitoring associated with the Original and Former Facilities were performed, including soil excavation and construction of a protective cap to prevent contact with separate-phase hydrocarbons (SPH) and soil with chemical concentrations that are above human health exposure limits.

In September 2016, the DEQ requested that the Port enter the VCP to evaluate impacts resulting from use of aqueous film forming foam (AFFF) that contained per- and polyfluorinated alkyl substances (PFAS). The DEQ's request followed the U.S. Environmental Protection Agency (EPA) publishing a provisional Health Advisory (HA) for two PFAS chemicals of 70 nanograms per liter (ng/L; combined PFOA and PFOS) for drinking water. The DEQ also requested that the Port evaluate current concentrations of hydrocarbons and volatile organic compounds (VOCs) previously identified, remediated, and monitored between 1994 and 2007.

Investigation activities commenced in April 2017 with sampling of select existing monitoring wells located in the fire training facilities vicinity. Subsequent activities conducted in August through October 2017 included water level monitoring and sampling of five existing monitoring wells, installation of 25 shallow borings for collection of soil and groundwater samples to evaluate potential source areas and the extent of impacts to groundwater, collection of two deep groundwater samples below the Site, collection of three surface water samples, collection of three stormwater samples, collection of three composite sediment samples, and completion of a stormwater conveyance system video survey.

Screening levels were used to assess the risk to potential receptors from constituents detected in the various media evaluated in this investigation. In general, DEQ Risk-Based Concentrations (RBCs) for Ingestion and

Inhalation of Tapwater for Residential receptors and DEQ Level II Ecological Risk Screening Level Values (SLVs) for Surface Water (Aquatic Life) were used to evaluate total petroleum hydrocarbons (TPH), metals, VOCs, polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs). There are currently no applicable Oregon PFAS criteria for groundwater, soil, surface water, or sediment. Risk-based screening levels for PFAS for human health and ecological receptors were reviewed for Oregon DEQ, EPA, other U.S. states, and countries globally. Based on these screening levels, a hierarchy was identified, and screening levels selected to evaluate PFAS concentrations detected in groundwater, soil, stormwater, and surface water during this investigation.

Results of the investigation indicate that concentrations of TPH, metals, VOCs, PCBs, and PAHs exceeding applicable SLVs are confined to the area surrounding wells MW-10A and MW-11 in the vicinity of the original fire training facility. Metals concentrations that exceed applicable SLVs appear to be background. PFAS concentrations in shallow groundwater exceeded the selected SLVs; however, based on the results of this investigation, the lateral extent of PFAS impacts to shallow groundwater has been delineated to the SLVs to the north, south, and east of the fire training facilities. The deep groundwater samples indicate that PFAS compounds are present beneath the fire training facilities in the shallow Lower Overbank Deposits (OD) at concentrations above the SLVs, but in the Columbia River Sand Aquifer (CRSA) detected concentrations are below SLVs. As an additional action to evaluate potential impacts to the groundwater aquifers in and around the Site, the Port also collected a groundwater sample from a newly installed well at the PDX Quick Turnaround (QTA) Facility, located approximately 1.3 miles east-southeast of the fire training facilities and screened from 145 to 200 feet below ground surface (bgs) in the CRSA. PFAS compounds were not detected in the sample collected from the QTA well, demonstrating that PFAS detected at the fire training facilities are not migrating toward the City of Portland Columbia South Shore Wellfield.

Results from the four soil samples analyzed for PFAS compounds indicated concentrations below selected human health risk-based screening levels for occupational direct contact. Soil samples exceeded the conservative protection of residential drinking water screening level.

Stormwater and surface water samples were collected from access points within the stormwater conveyance system, at the conveyance system outfall, at two surface locations downstream of the outfall, and from a drainage ditch located northwest of the facilities. In addition, a video survey was performed to assess the integrity of the conveyance system pipe and identified areas of seepage in portions of the pipe beneath the fire training facilities. The video survey suggests that groundwater infiltration is occurring, and PFAS were detected in stormwater and surface water (in drainage ditches). Detected concentrations in surface water offsite were below selected SLVs.

One five-point composite sediment sample was collected from surface sediment in a ditch located approximately 50 feet downstream of the stormwater conveyance system outfall. PFAS compounds were not detected above the laboratory method reporting limit in the composite sediment sample.

1.0 Introduction

This Original and Former Fire Training Facilities Investigation Results Report (the Report) presents the results for collection and chemical analysis of soil, groundwater, stormwater, surface water, and sediment samples located in the vicinity of, or potentially impacted by, the Original and Former fire training facilities (Original and Former Facilities; the Site) at Portland International Airport (PDX; Figures 1 and 2). The report also provides the results of a stormwater conveyance system camera survey to evaluate the potential for groundwater infiltration to the stormwater facilities. Work at the Site is being conducted with oversight from the Oregon Department of Environmental Quality (DEQ) in accordance with the Voluntary Cleanup Agreement (VCP) between the DEQ and the Port of Portland (Port) for ECSI No. 3324, dated February 8, 2017. This investigation was conducted in accordance with the Reconnaissance Well Sampling Work Plan, Investigation Work Plan, and Investigation Work Plan Amendment submitted to DEQ on April 13, August 29, and September 19, 2017, respectively (Apex, 2017a; Apex, 2017c; Apex 2017d).

1.1 Purpose

The purpose of the sampling described in this report was to assess and delineate the extent of shallow groundwater impacts and identify potential impacts, if any, to soil, deep groundwater, stormwater, surface water, and sediment associated with historical fire training practices at the Site.

1.2 Scope

This Report documents the activities, methods, work plan deviations, and results of sampling and assessment completed in accordance with the Reconnaissance Well Sampling Work Plan, Work Plan and Work Plan Amendment. The investigation included the following tasks:

- Reconnaissance well sampling in April 2017, included the collection of 14 shallow groundwater samples (including one duplicate sample) from 13 existing site monitoring wells and analysis for diesel- and oil-range total petroleum hydrocarbons (TPH), volatile organic compounds (VOCs), polychlorinated biphenyls (PCBs), PAHs, metals, and certain per- and polyfluorinated alkyl substances (PFAS; a component of aqueous film forming foam [AFFF]). Well MW-12 was not sampled due to the presence of separate-phase hydrocarbons (SPH). PFAS samples were analyzed for the fourteen PFAS compounds included in the 2012 U.S. Environmental Protection Agency (EPA) third Unregulated Contaminant Monitoring Rule (UCMR 3). The UCMR 3 identifies the list of unregulated contaminants to be monitored by public water systems in accordance with the 1996 Safe Drinking Water Act (SDWA).
- Collection of shallow groundwater samples from 4 existing site monitoring wells, including select wells in the vicinity of the Former Facility that were not sampled during the April 2017 event. These samples were analyzed for the fourteen PFAS compounds included in the 2012 EPA UCMR 3.

- Collection of a groundwater sample from monitoring well MW-4 for Total Oxidizable Precursor (TOP) Assay analysis to identify the sum of PFAS that could degrade in the environment to perfluorooctanoic acid (PFOA). Well MW-4 was selected for additional sampling and TOP Assay analysis on the basis of having the highest combined concentration of perfluorooctane sulfonate (PFOS) and PFOA among samples collected as part of the April 2017 reconnaissance groundwater monitoring event.
- Collection of shallow groundwater and soil samples from 20 borings in the vicinity and adjacent to the Original and Former Facilities to delineate the extent of shallow groundwater impacts associated with historical fire training activities. Groundwater samples were analyzed for PFAS. Selected soil samples were analyzed for PFAS to assess if soil may be an ongoing source to groundwater.
- Collection of two shallow groundwater samples from borings (Boring I and J) installed in the field northwest of the fire training facilities where reclaimed fire training facility water was land applied. The samples were analyzed for diesel- and oil-range TPH, VOCs, total and dissolved metals (arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver), PAHs, PCBs, and PFAS.
- Collection of one shallow groundwater sample from Boring Q installed adjacent to the stormwater sewer line downstream of the Original Facility to assess if infiltration from the storm sewer is a pathway for groundwater migration. The sample was analyzed for PFAS.
- Collection of deep groundwater samples at approximately 40 and 61.5 feet below ground surface (bgs) to evaluate vertical contaminant migration. The explorations were conducted adjacent to the Former Facility and monitoring well MW-4, presumed to be the source area and exhibiting the highest combined PFOS/PFOA concentration in groundwater sampling conducted in April 2017. Samples were analyzed for PFAS.
- A stormwater conveyance system camera survey was conducted in the stormwater conveyance line that runs adjacent to the Original Facility and under the Former Facility to evaluate the condition of the lines and identify potential leaks or pathways for groundwater discharge. Passing beneath and adjacent to the facilities, the conveyance line receives stormwater runoff from the vicinity of the Original and Former Facilities and appears to control shallow groundwater.
- Collection of stormwater from stormwater sewer line access points upstream and downstream of the fire training facilities (MH-1 [STSMH125] and MH-2 [STSCB3228]). Samples were analyzed for PFAS.
- Collection of surface water from the drainage ditch northeast of the Original Facility to assess shallow groundwater infiltration to drainage ditches. The sample was analyzed for PFAS.
- Collection of stormwater and sediment from the outfall (Outfall 1N) that discharges stormwater runoff from the vicinity of the Original and Former Facilities. The samples were analyzed for PFAS.

- Collection of surface water samples downstream of Outfall 1N at the western extent of Port property (SW-2) and in a Multnomah County Drainage District (MCDD) drainage ditch prior to being pumped into the Columbia Slough (SW-3).
- Record groundwater elevation data in April and September 2017 from the existing monitoring well network to support gradient mapping and evaluation for groundwater migration within and around local stormwater conveyances.
- Collection of a groundwater sample from the PDX QTA well located approximately 520 feet southeast of the air traffic control tower in the PDX QTA Facility and approximately 1.3 miles east-southeast of the Original and Former Facilities. The well is screened from 145 to 200 feet below ground surface in the Columbia River Sand Aquifer (CRSA).

The results of these activities are discussed in further detail within this Report.

2.0 Background

This section presents a brief description of the Site, its history, and available physical and chemical data. Information included in this section was obtained from previously completed site investigations and related work conducted within the vicinity of the Site.

2.1 Site Location and Description

The current, original, and former fire training facilities (herein the Current Facility, the Original Facility and the Former Facility, and collectively "the fire training facilities"), are located in the northwest portion of PDX (shown on Figures 1 and 2). Portions of the Site have been actively used for aviation firefighting drills since 1963. According to Port records, the Original Facility was used from approximately 1963 until the early- to mid-1970s, after which the Former Facility was used for training exercises until 1989. The Current Facility has been used since approximately 1989.

Some live fire exercises used water and retardant firefighting foams (i.e., AFFF) as part of training, in equipment and to extinguish specific types of training fires. The Current Facility is lined to reduce the potential for introduction of chemicals to the subsurface; however, the Original and Former Facilities were not lined.

PDX and its fire department are regulated under Federal Aviation Administration (FAA) and National Fire Protection Association (NFPA) regulations and guidance which specify the AFFF type, testing, use, and training that is required for use of AFFF on commercial aviation facilities. The PDX fire department has followed these regulations and standards of practice which has resulted in the use of PFAS-containing AFFF since the late 1960s.

2.2 Site History

From 1988 through 2017, site characterization, cleanup actions, and groundwater monitoring have been conducted at the Site, including soil excavation and construction of a protective cap to prevent contact with separate-phase hydrocarbons (SPH) and soil with chemical concentrations that are above human health exposure limits. Previous investigations have indicated that a variety of chemical substances (used oil, gasoline, diesel fuel, JP-4 fuel, acetone, and solvents) have been applied to the ground surface and mock aircraft, then ignited for training purposes. Soil and groundwater at the fire training facilities contain petroleum hydrocarbons and associated constituents (e.g., polycyclic aromatic hydrocarbons [PAHs]) from fuels used for training fires, and components of AFFF are present in groundwater. Separate-phase hydrocarbons have historically been present in one monitoring well (MW-12). Groundwater monitoring and/or limited, passive residual SPH removal was conducted at the Site through 2007.

The following provides a summary of the investigations completed at the fire training facilities.

- 1988 Site Characterization – The Former Facility was first investigated in 1988 by Roger N. Smith and Associates (RNSA) to assess if contamination of this area would interfere with construction of the Current Facility. RNSA excavated 20 test pits to a maximum depth of 10.5 feet below ground surface (bgs) and collected surface and subsurface soil samples. Petroleum hydrocarbons and related VOCs and semi-volatile organic compounds (SVOCs) were detected in soil. Petroleum hydrocarbons were detected at concentrations up to 175,000 milligrams per kilogram (mg/kg). Metals in soil were generally consistent with background. VOCs were detected in groundwater.
- 1994 Century West Characterization – Century West conducted site characterization to evaluate the nature and extent of impacts to soil and groundwater from fuels used during fire training activities. Century West excavated 10 test pits, completed 33 soil borings, and installed 9 groundwater monitoring wells in the vicinity of both the original and former fire training facilities. Total petroleum hydrocarbons were detected in soil at up to 32,000 mg/kg and 14,000 mg/kg at the original and former fire training facilities, respectively. VOCs and PAHs were also detected in soil. Metals in soil were consistent with background. VOCs and PAHs were detected in groundwater.
- 1996 Geraghty & Miller Investigation – Geraghty & Miller completed 12 borings and five monitoring wells and collected 14 surface soil samples at the original and former fire training facilities. TPH was detected in soil at up to 24,000 mg/kg and 14,000 mg/kg at the original and former fire training facilities, respectively. VOCs and PAHs were also detected in soil. Metals in soil were consistent with background. Polychlorinated biphenyls were detected in two samples. Groundwater monitoring showed that the gradient was toward a nearby storm sewer. VOCs, PAHs, and bis(2-ethylhexyl)phthalate were detected in groundwater. Lead in groundwater was likely consistent with background.
- 1996 Remedial Action – Beginning in 1996, the Port capped the Original and Former Facilities and implemented long-term groundwater monitoring as a remedial alternative. The protective cap

prevents direct contact with soil containing petroleum hydrocarbons and related constituents. The cap generally consists of a demarcation layer and a gravel base. Portions of the cap expected to receive greater vehicle traffic include a cement-treated gravel base or asphalt-concrete. The demarcation layer was constructed with a 5-mil, white, low-density polyethylene (LDPE) material overlain by a medium-weight, woven, polypropylene geotextile. The LDPE material served as a visible marker separating the aggregate base from underlying soils containing residual contaminants.

- 2001 Hart Crowser Groundwater Sampling Adjacent to Storm Sewer Line – In May 2001, Hart Crowser completed a test pit exploration adjacent to the storm sewer pipeline that runs west of the Original Facility area and runs west of the Former Facility area. Groundwater was encountered at a depth of about 7 feet bgs. After the groundwater that initially entered the excavation was purged, a groundwater sample was collected from the sand around the sewer pipeline. The groundwater sample was analyzed for PAHs and for benzene, toluene, ethylbenzene, and xylenes (BTEX), and neither PAHs nor BTEX compounds were detected in the test pit groundwater sample (Hart Crowser, 2001).
- Groundwater Monitoring: 1994 to 2007 – Groundwater sampling from monitoring wells was conducted quarterly from 1994 to 1996, semi-annually in 1997, and annually from 1998 through 2007. The monitoring consistently showed a groundwater gradient toward the stormwater conveyance system. Early sampling identified VOCs and PAHs above human health and ecological screening levels. By 2007, only benzene in one well (MW-12) was above screening levels.
- Separate Phase Hydrocarbon Removal 1996 to 2007 – Beginning in December 1996, removal of SPH using a sorbent sock was conducted in well MW-12. The thickness of SPH was measured during each groundwater monitoring event and the sorbent sock removed and/or replaced as appropriate. (Hart Crowser, 2002). The sorbent socks installed from 1998 through 2007 had no indications of hydrocarbon (i.e., no visual observation of staining) absorption (Ash Creek Associates, 2007) and ceased in 2007.

2.3 PFAS Regulatory Status

Since the 1940's PFAS have been used in many industrial and commercial applications. The most extensively produced PFAS chemicals in the United States were PFOA and PFOS. By 2002, all production of PFOS had been voluntarily discontinued by manufacturers in the United States. In 2015, as part of the PFOA Stewardship Program, eight major U.S. chemical manufacturers agreed to eliminate production of PFOA. The U.S. EPA amended the Significant New Use Rule to include PFAS under the Toxic Substances Control Act and in January 2015 required manufacturers and importers to notify the U.S. EPA at least 90 days prior to starting or resuming use of PFOA and related compounds. PFAS are now regulated and phase-outs of PFOA/PFOS and precursor compounds are established in the USA, EU, Canada, and Australia.

In 2016, the U.S. EPA established a provisional Health Advisory (HA) level of 70 nanograms per liter (ng/L) for combined concentrations of PFOS and PFOA in drinking water. This provision was updated in 2016 to

include chronic exposure of PFOS and PFOA combined. Health advisories provide information on contaminants that can cause human health effects and are known or anticipated to occur in drinking water. EPA's health advisories are non-enforceable and non-regulatory and provide technical information to states agencies and other public health officials on health effects, analytical methodologies, and treatment technologies associated with drinking water contamination. Additionally, in 2012 PFAS compounds, including PFOS, PFOA, perfluorononaoic acid (PFNA), perfluorohexane sulfonic acid (PFHxS), perfluoroheptanoic acid (PFHpA), and perfluorobutane sulfonic acid (PFBS),, were added to the Unregulated Contaminant Monitoring Rule (UCMR) to be monitored in public water supply systems. EPA uses the UCMR to collect data for contaminants that are suspected to be present in drinking water and do not have health-based standards set under the Safe Drinking Water Act (SDWA).

2.4 Site Geology and Hydrogeology

Site Geology. The near surface geology in the site vicinity is characterized by Pleistocene to recent alluvial deposits, consisting of unconsolidated, interbedded silts, sands, and gravels, overlying poorly to moderately consolidated Troutdale Formation conglomerates, with thin interbeds of claystone, siltstone, and sandstone. From the ground surface, down, the geologic units in the vicinity of the Site are Fill, Overbank Deposits (OD); Columbia River Sand Aquifer (CRSA); Troutdale Gravel Aquifer (TGA); Confining Unit 1 (CU1), Troutdale Sand Aquifer (TSA), Confining Unit 2 (CU2), and Sand and Gravel Aquifer (SGA).

The geology beneath the Site consists predominantly of fill, including silt or fine- to medium-grained sand (dredge sand), to a depth of 4 to 5 feet bgs overlying the OD consisting of layers of silty clay, silt, silty sand, and sandy silt. Within the native silty OD, an approximately 5-foot-thick layer of fine sand is present beneath the site at depths ranging from 10 to 17 feet bgs. Based on boring log MTD-1, installed approximately 2,000 feet north of the fire training facilities, and deep Boring M installed during this investigation, the CRSA has been observed at approximately 56 feet bgs, the TGA at approximately 280 feet bgs, CU1 at approximately 350 feet bgs, the TSA at approximately 420 feet bgs, and the SGA at approximately 570 feet bgs (Hart Crowser, 2004).

Site Hydrogeology. Aquifers in the OD (unconsolidated alluvial deposits) are generally unconfined and localized due to the heterogeneity of the deposits with the water typically present at 10 to 20 feet bgs. Water quality and hydraulic conductivity are highly variable. Shallow groundwater flow beneath the airport is controlled by surface water features (e.g., ditches, stormwater lines, Columbia River, and Columbia Slough) and groundwater elevations observed beneath the fire training facilities suggest a hydraulic gradient toward the storm sewer. Groundwater recharge in the OD occurs from rainfall infiltration from unpaved areas, irrigation, or downward migration of perched water from the Fill. Groundwater from the OD is typically expected to discharge to the Columbia River either directly through the OD, and/or indirectly through the underlying CRSA. In general, CRSA groundwater discharges to the Columbia River (except during high Columbia River stage). Regionally, the CRSA is also used as a source of drinking water.

As detailed in the Beneficial Land and Water Use Survey Update prepared by Apex in 2012, groundwater underlying the PDX property is not designated for a drinking water use. The predominant use of groundwater in the immediate vicinity of PDX is for irrigating landscaped areas and golf courses. No golf courses are present on Port property; however, several are located immediately adjacent to PDX. Otherwise, domestic use is limited to two residential areas southwest of the project site, and two marinas north of the airport. According to an online review of the Oregon Water Resources Department Well Log Query Report conducted on December 6, 2017, the closest domestic water well is located 0.8 mile northeast and cross-gradient to the Original and Former Facilities. Groundwater is also used for industrial purposes southwest of PDX and along Columbia Boulevard to the south. Water wells obtain groundwater from the CRSA, TGA, or deeper aquifers (Apex, 2012). No water wells were identified that utilize groundwater from the Fill or OD.

The City of Portland (City) also maintains a well field to the southeast of the PDX property, the City Columbia South Shore Well Field (CSSW). The City uses the CSSW both as an emergency backup supply and occasionally to seasonally augment the primary drinking water supply. The CSSW has municipal wells installed in the CRSA, TSA, and SGA (City of Portland, 2014). The CSSW has been used in its emergency capacity 12 times and for seasonal augmentation or maintenance 24 times since 1985 (City of Portland, 2017). The closest City water supply well is completed within the TSA and located over 3 miles southeast of the fire training facilities.

Based on monitoring conducted since 1994 at the Site, groundwater levels are generally at a depth of 10 feet bgs and fluctuate approximately 2 to 3 feet seasonally with lower water levels in the summer and fall. The hydraulic gradient is typically to the south and is influenced by the stormwater conveyance system (Ash Creek, 2007). Groundwater elevation data are discussed in greater detail in Section 4.3.3.

2.5 Screening Levels

Currently, there are no applicable DEQ screening levels for PFAS in groundwater, stormwater, surface water, sediment, or soil. To assess the potential risk posed by constituents detected in the various media evaluated in this investigation, the potential Site receptors and exposure pathways were identified and screening levels developed by the EPA, other U.S. states, and countries globally were surveyed and then selected based on receptor and pathway. This section presents the receptors and exposure pathways identified for the Site followed by the screening levels selected.

Potential receptors at the Site generally consist of human and ecological receptors. The Site is located entirely within PDX in an area that is not used on a regular basis. Additionally, for protection of aircraft, wildlife is actively discouraged from using the area. Groundwater is generally not used at the Site. Potential uses on nearby properties include irrigation and discharge to surface water. Beyond PDX, groundwater is used for drinking water, including domestic wells and the City of Portland Wellfield to the east. Stormwater from the Site, including stormwater that may include infiltrated groundwater, discharges to surface ditches on PDX and

adjacent industrial land. From the ditches, water is pumped to the Columbia Slough. Based on this summary of land and water use, the following identifies the receptors and exposure pathways.

- Human Health
    - Direct contact with soil – Occupational
    - Drinking water – Residential (as a conservative measure)
    - Direct contact with surface water/sediment - Construction Worker
    - Soil leaching to groundwater (protection of residential drinking water; as a conservative measure)
- Ecological
    - Direct contact with surface water
    - Direct contact with sediment

Screening levels were selected for these potential receptors and pathways to assess the potential risk posed by constituents detected in the various media evaluated in this investigation. DEQ Risk-Based Concentrations (RBCs) for Ingestion and Inhalation of Tapwater for Residential receptors and DEQ Level II Ecological Risk SLVs for Surface Water (Aquatic Life) were used as conservative screening levels for TPH, VOCs, PCBs and metals (Table 4).

Human health and ecological screening criteria or health advisories have been issued for PFOS, PFOA, and other PFAS compounds by EPA, several U.S. states, and in territories and countries globally. In general, screening levels for this assessment were selected using the receptors and pathways identified above using the following hierarchy:

1. Applicable or relevant DEQ risk-based criteria or guidance;
2. Applicable or relevant EPA risk-based criteria or guidance or advisory;
3. Relevant criteria or guidance from other states; or
4. Relevant criteria or guidance from other countries.

Following this selection process, if screening levels were identified for multiple states, the conservative screening level value for the receptor and pathway was selected. Although groundwater screening levels were identified for several states, the Port voluntarily used the conservative EPA HA to screen groundwater analytical data for this investigation. Screening levels selected for the potential Site receptors and pathways are as follows:

- Human Health

- Direct contact with soil (Occupational) – EPA RSL for PFOS, PFOA, and PFBS and Texas protective concentration levels for commercial land (30 acres) for remaining 11 PFAS compounds.
- Drinking water (Residential) – EPA HA for PFOS and PFOA and Texas residential drinking water for remaining 12 PFAS compounds.
- Direct contact with surface water/sediment (Construction Worker) – Maine screening level for PFOS and PFOA. SLVs for remaining PFAS compounds were not identified during the survey.
- Soil leaching to groundwater (protection of residential drinking water) - EPA RSL for PFOS, PFOA, and PFBS and Texas protective concentration levels for residential land (30 acres) for remaining 11 PFAS compounds.

- Ecological
  - Direct contact with surface water – Michigan water quality values aquatic species (final aquatic value) for PFOS and PFOA. SLVs for remaining PFAS compounds were not identified during the survey.
  - Direct contact with sediment – PFAS compounds were not detected in sediment samples therefore no SLV was selected.

Appendix A includes tables presenting results of the survey of drinking water, groundwater, surface water, soil, and sediment screening levels. These tables consist of screening levels available as of June 2017. Based on the receptors/pathways identified above and the values presented in Appendix A, selected screening levels for PFAS are applied in Tables 2 through 8.

3.0 Field Activities

3.1 Investigation Preparatory Activities

Property Access. Apex provided notification to Port personnel and Port Operations (OPS) to coordinate access to the Site at PDX. The notifications were submitted to OPS a minimum of one week in advance. All unbadged Apex employees and subcontractors were escorted by badged Apex employees.

Flagging/Barricading: Portions of the work were performed south of Taxiway B and north of the main runway during planned taxiway maintenance closure. Work areas were delineated with cones and vehicles with amber flashing beacons. During field investigation activities, airside Port Airport Operations notifications were completed in accordance with Port requirements.

Underground Utility Location. Prior to conducting ground disturbance activities, Apex mobilized to the Site to mark the proposed sampling locations with marking paint and notified the Oregon Utility Notification Center in accordance with requirements specified in Oregon Administrative Rules (OAR) Chapter 952. Because underground utility operators do not mark on private property and because the drilling activities were performed inside the secure area of PDX, Port personnel conducted an underground utility locate to mark underground utilities located within the proximity of each proposed sampling location prior to performing the subsurface work.

Site Health and Safety Plan. A Site-specific health and safety plan (HASP) was prepared for the activities. The HASP was prepared in general accordance with the Occupational Safety and Health Act (OSHA) and the OAR. A copy of the HASP was maintained on-Site during the field activities.

Prior to performing on-Site work, Apex prepared a Job Safety Analysis (JSA) and HASP guiding Site- and project-specific activities, risks, and safety protocols. All field staff and subcontractor personnel supporting the project reviewed and agreed to abide by the HASP. Safety topics were refreshed daily with the field crew using a daily tailgate safety meeting, conducted by Apex's Site Supervisor or Site Safety Officer.

3.2 Methods and Procedures

3.2.1 PFAS-Specific Sampling Procedures

To reduce the chance of inadvertent PFAS contamination of samples, Apex sampling personnel and subcontractors avoided using PFAS-containing items during the sampling process. Items commonly used in sampling processes that may contain PFAS include polytetrafluoroethylene (PTFE, also known as Teflon), low-density polyethylene (LDPE), and polypropylene. Other common items that may contain PFAS include aluminum foil, post-it notes, waterproof field books, markers, chemical ice packs (e.g., blue ice), certain decontamination soaps, and certain product packaging (e.g., such as that found on pre-wrapped foods and snacks). Similarly, many clothing items contain PFAS, such as those coated with Teflon or incorporating a Gore-Tex membrane. Clothing items worn by Apex field staff had been washed at least six times and known PFAS-containing products were avoided during sample collection. In addition, field personnel avoided the use of PFAS-containing products such as cosmetics, moisturizers, insect repellant, sunscreen, and hand cream. Nitrile gloves were used during all sample collection activities, including equipment set-up, sample collection, and sealing of containers. PFAS contamination prevention protocols were reviewed with subcontractors and personnel daily during the field activities.

3.2.2 Stormwater Conveyance Line Camera Survey

On September 29, 2017, Apex subcontractor Pacific INT-R-TEK conducted a video survey of approximately 1,500 feet of the 36-inch diameter stormwater conveyance system pipe located beneath the Site from manhole STS CB 3228 to STS MH 5094. The survey was conducted to assess the integrity of the stormwater line that

flows from northeast to southwest beneath the Original and Former Facilities (Figure 3). The video camera unit, manufactured by Aries Industries, Inc., was a two-piece system consisting of a motorized wheel transporter and the camera. Approximately 680 feet of the surveyed stormwater system is upstream of the Former Facility; approximately 500 feet is directly underneath the Former Facility; approximately 220 feet is downstream of the Former Facility; and approximately 100 feet is downstream of the Original and Former Facilities. Figure 3 presents the extent of the surveyed conveyance system. The total length of the video survey was completed in five segments in order to span the distance between catch basin or manhole access points, to allow transfer of the camera over the catch basin sumps at the intersection of each segment, and to document any identification tags at each launch location. Figure 3 shows the schematic of the stormwater system and the segments of the stormwater system that were video surveyed.

3.2.3 Shallow Soil Boring Installations

Under the supervision of Apex, Steadfast Services NW, LLC (Steadfast) of Vancouver, Washington installed twenty-three soil borings (Boring A through L, and Boring N through X) using a Geoprobe push-probe to an approximate depth of 15 feet bgs or to first encountered groundwater from August 28 through 29 and September 27 through 29, 2017 (Figure 6). Soil cores were extracted, and soil lithology and conditions logged in general accordance with ASTM 2487/2488. Descriptions included visual indications of impacts. Soil cores were field screened at approximately 2-foot intervals for VOCs using a photoionization detector (PID) and for SPH using sheen tests.

A field log of lithology and soil conditions was maintained for the borings and the location recorded using a handheld global positioning system (GPS) unit. Lithologic logs are included as Appendix C. Drilling equipment (i.e., direct push rods, macro-core, etc.) were decontaminated before and after each boring.

A minimum of two soil samples was collected from each location for possible chemical analysis. Samples were collected at 0.5- to 1-foot bgs and at the soil-water interface (depth determined based on groundwater level at the time of drilling estimated from visual indicators of groundwater). Additional soil samples were collected at Boring O and Boring V locations based on field screening indications.

One grab groundwater sample was collected from each exploration. Field parameters, including pH, temperature, and electrical conductivity were recorded during groundwater sampling. Samples were transferred into laboratory-supplied containers, stored at 4 degrees Celsius (°C), and submitted to state-certified laboratories. Samples analyzed for PFAS by EPA Method 537 (modified) and TOP Assay were submitted to Vista Analytical (Vista) in El Dorado Hills, California. Groundwater samples collected from Borings A, D, I, and J were submitted to and analyzed by Apex Laboratories (Apex Lab) of Tigard, Oregon for diesel- and oil-range TPH by Method NWTPH-Dx with silica gel cleanup and VOCs by EPA Method 8260. Field observations and measurements made during groundwater monitoring were recorded in field notes. Groundwater monitoring field sheets are included as Appendix E.

3.2.4 Deep Soil Boring Installations

Under the supervision of Apex, Cascade Drilling (Cascade) of Clackamas, Oregon installed two soil borings (Boring M Deep and Boring M Shallow) to collect grab groundwater samples at depth. The borings were advanced using a sonic drill rig on October 2 and 3, 2017 (Figure 6). The purpose of the deep groundwater collection was to evaluate the potential for vertical contaminant migration resulting from impacts related to the Former Facility activities. The Boring M exploration locations were adjacent to and west of the Former Facility, and in the vicinity of monitoring well MW-4, in the area that exhibits the highest combined PFOS/PFOA concentration in groundwater sampling conducted in April 2017. Groundwater sample collection depths included one sample from the lower OD unit screened from 35 to 40 feet bgs, just above the CRSA regional aquifer, and one sample from within the CRSA unit screened from 56.5 to 61.5 feet bgs. Grab groundwater samples collected from these explorations were analyzed for PFAS.

Sonic drilling uses high-frequency, resonant energy to advance a core barrel or casing into subsurface formations. The method uses a dual-cased system, with inner core barrel advancement, followed by outer casing advancement to sleeve over the inner casing to create hole stability. For each interval, the 4-inch-diameter inner core barrel was advanced at 10-foot intervals into the subsurface, followed by the 6-inch-diameter outer casing. At each interval, the core barrel was then removed from the borehole and the soil was bagged for logging and sampling. By design, this process effectively isolates the inside of the drill core from the surrounding media, thus preventing cross-contamination. This process continued until the total depth was reached.

During installation of the deep boring, heaving sands were encountered below 70-feet bgs. The sands were heaving such that, with the outer 6-inch casing in place at 80-feet bgs, heaving sands were entering the casing and rising to a depth of 65-feet. An attempt to install a temporary well was made with the heaving sands at 65-feet bgs. When the outer casing was raised to this depth, the heaving sands rose to 55-feet bgs. Cascade attempted several clean-out runs to clear the heaving sands, but significant back-pressure and additional heaving sands were observed. To clear the heaving sands from the casing, Cascade injected approximately 45 gallons of potable water into the annular space between the casing and the tooling.

After injecting water and conducting the additional clean-out runs, the sand continued heaving and a maximum boring depth of 61.5 feet bgs was reached. A temporary well was installed at a depth of 61.5 feet bgs and screened from 56.5 to 61.5 feet bgs. Approximately forty-five gallons of water was purged from the temporary well and water parameter stabilization was confirmed prior to collecting a groundwater sample. Prior to the collection of groundwater samples, pH, conductivity, temperature, dissolved oxygen (DO) and oxidation-reduction potential (ORP) were documented.

Soil sampling for lithologic descriptions was conducted for the full length of the deep boring. Soil cores were field screened at approximately 2-foot intervals for VOCs and SPH using a PID, and for SPH using sheen

tests conducted on soil at approximately 2-foot intervals. Lithologic descriptions were completed in general accordance with ASTM 2487/2488. Lithologic logs are included in Appendix C.

Based on the heaving sands associated with the installation of the temporary well at Boring M Deep into the CRSA, a second boring (Boring M Shallow) was installed adjacent to the Boring M Deep location. For this location, a temporary well was installed in the lower OD at a depth of 40 feet bgs and screened from 35 to 40 feet bgs. Documentation of field parameters (pH, conductivity, temperature, DO, and ORP) was conducted prior to groundwater sample collection.

Grab-groundwater sampling procedures, sample handling, and quality assurance/quality control (QA/QC) procedures were completed in accordance with the Work Plan.

3.2.5 Groundwater Monitoring

Groundwater levels were measured on April 20 and September 26, 2017 from thirteen monitoring wells at the Site (Figures 2 and 5). The surface at well MW-5 was submerged by ponded water so the well was gauged on April 21, 2017, after the ponded water receded. Well MW-3 could not be opened due to monument damage and therefore was not measured. The well caps were removed and water levels allowed to equilibrate before the measurements were taken. The depth to groundwater, free product, and/or sheen were measured in each well to the nearest 0.01 foot using an electronic oil-water interface probe.

Groundwater samples were collected from six existing monitoring wells (MW-1, MW-3, MW-4, MW-7, MW-9, and MW-10A) in April 2017 and from four existing monitoring wells (MW-6, MW-8, MW-13, and MW-14) on September 26, 2017 (Figure 2). A duplicate sample was collected from monitoring well MW-6. Previously sampled during the April 2017 reconnaissance event and exhibiting the highest combined concentrations of PFOS and PFOA among the wells sampled, an additional groundwater sample was collected from well MW-4 on September 26, 2017 and analyzed for PFAS TOP Assay to identify the sum of PFAS that could be converted to perfluoroalkyl acids and to assess the potential PFAS environmental risk.

For samples collected from the monitoring wells, groundwater field parameters (pH, ORP, DO, specific conductivity, and temperature) were measured with a water quality meter using a flow cell connected to the discharge tubing of the sample pump. The turbidity of the water was monitored visually with color and clarity of the water recorded on the sampling data sheet. Purging was considered complete when the water quality parameters stabilized to within 10 percent and the water was visually clear for three consecutive three-minute intervals. Groundwater monitoring field sheets are presented in Appendix E.

3.2.6 Stormwater and Surface Water Sampling

Stormwater Conveyance System Sampling. On August 29, 2017, grab stormwater samples were collected from two access points along a stormwater conveyance line to assess the potential for PFAS-impacted

shallow groundwater infiltration into the conveyance system. The sampling locations are indicated on Figure 7. One access point (sample location MH-2 [STSCB3228]) was located approximately 700 feet upgradient of the Former Facility and a second access point (sample location MH-1 [[STSMH125]) was located approximately 350 feet downgradient of the Former Facility. Due to the confined space entry necessary for sample collection, manhole access was completed by subcontractor Terra Hydr with Apex oversight. Lab-specific containers were used for direct grab stormwater sample collection.

Outfall Sample Collection. On August 29, 2017 a grab stormwater sample was collected from the catch basin located directly upgradient of outfall OF1N (Figure 7). Due to the confined space entry necessary for sample collection at the OF1N access point, manhole access was completed by subcontractor Terra Hydr with Apex oversight. Lab-specific containers were used for direct grab stormwater sample collection.

Surface Water Sample Collection. On August 29 and September 28, 2017, three surface water grab samples were collected to assess PFAS concentrations in the vicinity of and downgradient of the Original and Former Facilities. Surface water was collected from the drainage ditch located approximately 180 feet north of the Original Facility at the culvert inlet to the stormwater conveyance system (sample location SW-1). The other two surface water grab samples were collected downstream of the Current and Former Facilities. Surface water sample SW-2 was collected from the drainage ditch at a location immediately east of the drainage ditch at its intersection with Sunderland Ave, approximately 1.1 miles southwest of the Site. Surface water sample SW-3 was collected from the drainage ditch near MCDD Pump Station #2, approximately 1.7 miles southwest of the Site. Each of the surface water sample locations are presented on Figure 7.

3.2.7 Sediment Sampling

On September 28, 2017, Apex mobilized to the outfall located southeast of the Deicing Treatment facility, approximately 4,400 feet west of the Site and downstream of surface water sample SW-1 and stormwater samples MH-1, MH-2, and OF1N-NW, to collect composite sediment samples at OF1N-SED (Figure 7). The composite samples were collected from an approximately 30-foot long section of the ditch, with the upstream end of the collection area located approximately 50 feet downstream of the outfall. The composite samples consisted of depth-discrete samples collected from 5 approximately equidistant sample locations within the sampling area. Depth-discrete samples included those collected from the 0- to 12-inch, 12- to 24-inch, and 0- to 24-inch depth intervals. These depths are based on the anticipated thickness of sediment over native soil. Each composite sample was homogenized before placing into the lab specific containers.

3.2.8 PDX Rental Car QTA Well

The PDX rental car Quick Turnaround Facility (New QTA) well is located approximately 520 feet southeast of the air traffic control tower in the PDX QTA Facility and approximately 1.3 miles east-southeast of the Original and Former Facilities. The New QTA is under construction and is scheduled to be completed in 2018. The new QTA well was started on May 24, 2017 and completed on September 20, 2017. The well is screened

from 145 to 200 feet bgs in the CRSA. The well will be used as a non-potable water source. Currently, there are no plans to supplement the municipal drinking water system from the new QTA well. A well construction log is included as Appendix F. The well location is shown on Figure 8.

The new QTA well was sampled by Apex on August 24, 2017 following purging and water quality sampling conducted by the Port's water well consultant. A grab groundwater sample was collected directly from the aboveground sampling valve associated with the well in general accordance with groundwater sampling procedures specified in the Work Plan.

3.2.9 Analytical Program

Chemical analyses were performed on the collected groundwater, stormwater, surface water, sediment, and select soil samples. Remaining soil samples were retained for potential future laboratory analysis. Samples were analyzed on a standard turnaround time (usually 14 to 21 business days depending on analyses). Analytical laboratory reports and a data quality review are provided in Appendix D.

Groundwater Samples. All groundwater samples were analyzed for PFAS. PFAS analysis by EPA Method 537 (modified) was conducted by Vista Analytical (Vista) of El Dorado Hills, California. Reported PFASs included fourteen compounds: PFBS, PFHpA, Perfluorohexane sulfonic acid (PFHxS), Perfluorohexanoic acid (PFHxA), PFOS, PFOA, Perfluorotetradecanoic acid (PFTeDA), PFNA, Perfluorodecanoic acid (PFDA), Perfluoroundecanoic acid (PFUdA), Perfluorododecanoic acid (PFDoA), Perfluorotridecanoic acid (PFTrDA), N-Ethylperfluoro-1-octanesulfonamidoacetic acid (N-EtFOSAA) and N-Methylperfluoro-1-octanesulfonamidoacetic acid (N-MeFOSAA). One groundwater sample collected from well MW-4 was analyzed for PFAS TOP Assay by TestAmerica Laboratories under subcontract to Vista. The groundwater samples collected from Borings A, D, I, and J were analyzed by Apex Laboratories (Apex Labs) of Tigard, Oregon for diesel- and oil-range TPH by Method NWTPH-Dx with silica gel cleanup and VOCs by EPA Method 8260. Groundwater samples from Borings I and J were analyzed by Apex Labs for total and dissolved metals (arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver) by EPA 6000/7000-series methods, PAHs by EPA Method 8270D (SIM), and PCBs by EPA Method 8082A.

Soil Samples. Soil samples from twenty borings were retained for potential future analysis, with the exception of the soil samples collected from Borings F, G, and M. Surface soil samples collected at a depth of 0.5- to 1-foot bgs from Borings F, G, and M and vadose zone sample from Boring M collected at a depth of 9.5- to 10-feet bgs were analyzed for PFAS by Vista using EPA Method 537 (modified).

Stormwater, Surface Water, and Outfall Samples. Stormwater, surface water, and outfall sediment samples were analyzed for PFAS by EPA Method 537 (modified). PFAS analysis was conducted by Vista.

3.2.10 Work Plan Deviations

Several deviations from the Work Plan and Work Plan Addendum occurred during the investigation. The following presents the deviation and the rationale for each task.

- Deep Boring Modifications. For deep (Lower OD and CRSA) groundwater sample collection, a single boring approach was presented in the Work Plan. In that scenario, prevention of cross-contamination was to be achieved using sonic drilling techniques and isolation using a packer-based, deployable sampling system to collect the depth discrete groundwater samples. It was later identified that the packer system could not be confirmed PFAS-free, therefore the conservative alternative methodology of installing temporary wells in two separate borings was used to reduce the potential of vertical groundwater cross-contamination.
- Surface Water Samples. Analytical results from stormwater (MH-1 and MH-2) and surface water (SW-1) samples were received prior to completion of the investigation tasks outlined in the Work Plan. Based on those results, additional surface water samples (SW-2 and SW-3) were collected from the drainage ditch locations downstream of Port outfall OF1N (Figure 7).
- Composite Sediment Samples. For the sediment sample proposed in the Work Plan downstream of outfall OF1N, the proposed sampling approach included a 5-point composite sample with subsample locations in a "star" pattern as requested by DEQ. At the time of sampling, it was determined that the drainage ditch width was too narrow at the proposed location to apply the "star" pattern. Instead, a linear arrangement of composite subsample locations was used, with alternating subsamples collected from the center, left, and right portions of the ditch channel.
- PDX New QTA Well Sample. During the investigation activities, it was identified that a non-potable water supply well had been completed on PDX property. Upon completion, a grab groundwater sample was collected from the PDX QTA well and analyzed for PFAS as an additional data point to evaluate the potential for deep groundwater contamination resulting from the impacts to shallow groundwater observed in the vicinity of the PDX fire training facilities. The well is located approximately 1.3 miles east-southeast of the Original and Former Facilities, between the Site and the City of Portland wellfield.

4.0 Investigation Results

The following sections present the investigation results of the camera survey and the analytical results of samples submitted for chemical analyses. Laboratory analytical reports and a review of laboratory data quality are included in Appendix D. Camera survey details are presented in Table 1, analytical results are summarized in Tables 2 through 4 and 6 through 8, and summarized on Figures 4, 6, and 7. Groundwater elevation data are presented in Table 5 and on Figure 5.

4.1 Stormwater Conveyance Line Survey

To assess the integrity of the stormwater system for the purpose of assessing the potential for groundwater impacts to surface water, a video survey was conducted within an approximately 1,500 feet section of 36-inch diameter concrete stormwater conveyance pipe that flows from northeast to southwest beneath the Original and Former Facilities. The survey was completed during the dry season (September), prior to seasonal rainfall and stormwater flow into the conveyance system. The survey was conducted from manhole STS CB 3228 to STS MH 5094, (Figure 3). In general, the conveyance system appears to be in good condition, with limited areas of observed seepage, fracturing, or deterioration. The stormwater line was surveyed in five separate segments, described in Table 1 and presented on Figure 3. An estimated 2 inches of water flow was observed along the entire length of surveyed pipe. A DVD of footage from the camera survey is included as Appendix B.

Details regarding observations made during the survey are included in Table 1. The following presents a description of seepage observations made during the camera survey from STS MH 3320A to STS MH 5094 (496 feet in length). This pipe segment is located beneath the west side of the Former Facility and just north of the Original Facility. At manhole STS MH 3320A, a 4-inch diameter lateral with a filter sock was observed protruding from the south just below the manhole cover. At 18 feet downstream from STS MH 3320A, a large piece of broken concrete was observed at the bottom of the pipe (likely from catch basin STS MH 3320A). At 112 feet downstream from STS MH 3320A, a 6-inch diameter PVC lateral joined the mainline from the south. Yellow staining and minor fractures in the pipe were observed at several locations throughout this segment of pipe. Groundwater seepage and a waxy yellow build-up were observed at several locations between 324 feet and 418 feet downstream of STS MH 3320A. Heavy seepage flow was observed at 334 feet. At 369 feet, heavy staining and seepage were observed in the pipe along with seepage and black staining at an access port on the top of the pipe.

4.2 Soil Analytical Results

Four soil samples were analyzed for 14 PFAS compounds, including samples collected from Borings F and G at a depth of 0.5- to 1-foot bgs and from Boring M at depths of 1.5- to 2-feet and 9.5- to 10-feet bgs. Soil analytical data are presented in Table 2. Figure 4 presents the PFOA and PFOS concentrations in soil.

Based on concentrations of PFOS and PFOA in shallow groundwater, shallow soil samples collected from Borings F and G were analyzed to assess for a potential source of impacts to groundwater. In both of the samples, 6 of the 14 PFAS compounds (PFHxA, PFHpA, PFOA, PFAS, PFNA, and PFDA) were present at concentrations above the method reporting limit (MRL) ranging from 2.03 micrograms per kilogram (µg/kg; parts per billion) for PFDA to 42.3 µg/kg of PFNA. PFOS concentrations were 6.31 to 268 µg/kg in Borings F and G, respectively, while PFOA concentrations were11.4 to 13.1 µg/kg, respectively.

Shallow native soil and vadose zone soil samples were analyzed from Boring M located adjacent to the Current and Former Facility. This location was in relatively close proximity to monitoring well MW-4, where

groundwater was observed to have the highest combined concentration of PFOA and PFOS during April 2017 reconnaissance well sampling. For the shallow native soil sample (beneath the gravel cap) collected at a depth of 1.5- to 2-feet bgs, PFOA and PFOS concentrations were 1.94 µg/kg and 120 µg/kg, respectively. The remaining PFAS compounds were not detected. Detected PFAS compounds in the vadose zone soil sample (9.5- to 10-feet bgs), included four of the short-chain PFAS (4 to 6 carbons; PFBS, PFHxA, PFHxS, and PFHpA) at concentrations ranging from PFBS at 5.16 µg/kg to PFHxS at 22.2 µg/kg. PFOA was detected at a concentration of 649 µg/kg and PFOS was not detected at a concentration above the MRL.

The detected concentrations of PFAS in soil are below the occupational direct contact selected SLV; however, detected concentrations of select PFAS exceed the selected SLV for protection of residential drinking water with exceedance ratios ranging from 1.1 for PFHpA to 320 for PFOS.

4.3 Groundwater Elevations

Groundwater levels were measured in Site wells on April 20 and 21, 2017 and on September 26, 2017 (except for well MW-3). Depth to groundwater ranged from 2.51 (MW-14) to 10.65 (MW-5) feet bgs in April and from 4.60 (MW-14) to 11.12 (MW-5) feet bgs in September. Groundwater elevations ranged from 8.63 to 15.23 feet above mean sea level (msl) in April and from 6.83 to 13.13 feet above msl in September. Groundwater elevations are presented in Table 5. Consistent with previous observations, the groundwater elevations suggest a hydraulic gradient to the southwest toward the storm sewer (Figure 5). SPH were present in well MW-11 (0.10 foot) in September and well MW-12 (0.15 foot and 0.12 foot in April and September, respectively). SPH was last observed in well MW-12 in April 1998 at a thickness of 0.03 foot. SPH had not been previously observed in well MW-11 (1994 to present).

4.4 Groundwater Analytical Results

4.4.1 Shallow Boring Groundwater Samples

Nine PFAS compounds (including PFBS, PFHpA, PFHxS, PFHxA, PFOS, PFOA, PFNA, PFDA, and PFUnA) were detected in one or more of the 23 groundwater samples collected from shallow boring locations. Detected PFOA concentrations in shallow groundwater ranged from 1.31 ng/L in Boring B to 8,810 ng/L in the Boring H groundwater sample. PFOS concentrations ranged from 1.70 ng/L in the Boring A groundwater sample to 3,330 ng/L in the Boring J groundwater sample. PFAS results for shallow groundwater samples are presented in Table 3 and on Figure 6. Concentrations of PFOS and PFOA generally attenuated with downgradient distance from the Original and Former Facilities. In general, PFOS compounds were present at higher concentrations than PFOA concentrations in the vicinity of the Original and Former Facilities.

In addition to PFAS analysis, groundwater samples from Borings I and J were analyzed for metals (total and dissolved), diesel- and oil-range hydrocarbons, polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs) in accordance with the Work Plan. Samples from Borings A and D were analyzed for

diesel- and oil-range hydrocarbons and VOCs. Arsenic (total and dissolved) was detected in groundwater samples from Borings I and J at concentrations above applicable SLVs for residential ingestion. Barium (total and dissolved) and lead (total) were detected in groundwater samples from boring locations I and J above the applicable SLV. These metal concentrations may represent background conditions. Diesel, oil, VOCs, PCBs and PAHs were not detected in the shallow groundwater samples from Borings I and J. Diesel, oil, and VOCs were not detected in the shallow groundwater samples from Borings A and D. Results for diesel, oil, VOCs, PCBs, metals and PAHs are presented in Table 4.

The detected concentrations of PFAS in shallow groundwater in Borings D through K, O, P, V, and X exceed the selected SLV for drinking water, with exceedance ratios of up to 160.

Evaluation of these results suggests that the lateral extent of shallow groundwater impacts has been delineated south and east of the fire training facilities, as represented by concentrations in Borings L, N, Q, R, S, T, U, and W below the selected SLV. In addition, the combined PFOS/PFOA concentrations are below the selected SLV at Borings A, B, and C, and less than 4 times the selected SLV level at Borings D, V, and X, indicating that PFAS impacts have been relatively well defined to the north and northeast. Boring locations H, P, and V (exceedance ratios of 126, 2.2, and 3.7, respectively), installed west of the Original and Former Facilities have combined PFOS/PFOA concentrations that exceed the selected SLV. Based on these results, additional investigation is needed to identify the lateral extent of PFAS impacts in shallow groundwater west of the Site.

4.4.2 Deep Boring Groundwater Samples

Groundwater samples were collected from Boring M Shallow at 40 feet bgs and Boring M Deep at 61.5 feet bgs. PFAS results for deep groundwater samples are presented in Table 3 and on Figure 6. The groundwater sample collected at 40 feet bgs had concentrations of PFOA at 61.5 ng/L and PFOS at 963 ng/L. The groundwater sample collected at a depth of 61.5 feet bgs had PFOA at 9.34 ng/L and PFOS at 60.5 ng/L; the combined concentration in the deeper sample is just below the selected SLV level of 70 ng/L. The combined concentration of PFOA and PFOS of groundwater at 40 feet bgs exceeded the selected SLV level for drinking water by a factor of 15.

4.4.3 Reconnaissance Groundwater Monitoring

Analytical results for the April 2017 reconnaissance groundwater monitoring, which included the collection of 14 shallow groundwater samples (including one duplicate sample) from 13 existing site monitoring wells that had been installed as part of prior Port investigation of the fire training facilities, identified detected concentrations of TPH, PAHs, and VOCs in well MW-11 (1,3-dichlorobenzene was detected in nine other Site wells); anthracene, fluorene, and PCBs in well MW-10A; and metals in each well. Table 4 presents the analytical results for TPH, VOCs, PAHs, PCBs, and metals.

The detected concentrations of PFAS in shallow groundwater in the existing monitoring well network exceeded the selected SLV with exceedance ratios ranging up to 3,000. PFAS results are presented in Table 3 and on Figure 6.

4.4.4 Groundwater – QTA Well

PFAS were not detected above the MRL in the PDX QTA well groundwater sample. The MRL for PFOA was 2.23 ng/L and 1.05 ng/L for PFOS. PFAS results are presented in Table 3.

4.4.5 Groundwater – PFAS TOP Assay

Total oxidizable precursor (TOP) assay analysis was performed on a groundwater sample collected from well MW-4. Current methodologies for the analysis of PFAS are designed to measure a discrete list of 14 to 30 compounds. There are many additional PFAS compounds that are not detected as discrete compounds by existing analytical methods. The purpose of the TOP assay is to assess for the presence of PFAS compounds that may, given time, weather to substances of concern such as PFOA.

TOP assay results are presented in Table 6. These results (based on one sample) indicate that there is little potential for the PFAS observed in the groundwater sampled from well MW-4 to degrade to PFOA over time.

4.5 Stormwater and Surface Water Analytical Results

Nine PFAS compounds (including PFBS, PFHpA, PFHxS, PFHxA, PFOS, PFOA, PFNA, PFDA, and PFUnA) were detected in one or more of the stormwater or surface water samples collected during the investigation. Detected PFOA concentrations in stormwater ranged from 175 ng/L in sample MH-2 to 1,220 ng/L in sample MH-1. PFOS concentrations ranged from 28.0 ng/L in sample MH-2 to 6,610 ng/L in sample MH-1. PFAS results for stormwater and surface water are presented in Table 7. As presented on Figure 7, sample location MH-2 (STSCB3228) is upstream of the Original and Former Facilities and sample MH-1 (STSMH125) is on the downstream side of the Site, adjacent to the Original Facility. Detected PFOA concentrations in surface water ranged from 76.8 ng/L in sample SW-3 to 1,110 ng/L in the sample SW-1 (Ditch 1). PFOS concentrations ranged from 323 ng/L in sample SW-3 to 14,500 ng/L in sample SW-1 (Ditch 1) in surface water samples. As presented on Figure 7, sample location SW-3 is the furthest downgradient of the Site and sample location SW-1 (Ditch 1) is northwest of and in close proximity to the Site. The surface water concentrations of PFOS and PFOA detected in sample location SW-3 had the lowest relative concentrations of PFAS indicating that PFAS concentrations in stormwater attenuate with distance from the source area.

The PFOS concentration observed at sample location SW-1 (Ditch 1), is the highest relative concentration observed outside of the source area (wells MW-3 and MW-4) while the PFOA concentration is consistent with and the same order of magnitude as the concentrations observed in the source area (Figures 6 and 7). Groundwater elevation data were used to compare depth to groundwater on either side of the drainage ditch

to identify if impacted shallow groundwater was likely interfacing with surface water. Depth to groundwater is contained on lithologic logs in Appendix C. On September 28, 2017, Borings H, I, and J were installed. Depth to groundwater at Borings I and J, east of the drainage ditch, were identified to be 5.70 and 4.66 feet bgs, respectively, and the depth to groundwater at Boring H was 11.65 feet bgs, west of the drainage ditch. The variation of up to 7 feet of groundwater elevation in approximately 700 feet indicates a strong potential for groundwater seepage into the drainage ditch and surface water systems in and around the Site. Based on the concentrations observed in the stormwater and surface waters samples collected on and offsite; results of the stormwater conveyance system survey detailed above, and groundwater elevation data collected during installation of borings H, I, and J, PFAS-impacted shallow groundwater is likely entering the surface water and stormwater systems.

Detected concentrations of PFAS in stormwater from samples MH-1 and OF1N-NW and surface water from drainage ditch (sample SW-1) exceeded the selected SLV for construction workers. Exceedance ratios ranged from 1.3 for PFOS to 5.5 for PFOA. Concentrations detected in sample location SW-3, located the furthest downgradient from the Site, do not exceed the SLV for construction workers. Analytical results of stormwater and surface water samples did not exceed selected SLVs for aquatic species.

4.6 Sediment Analytical Results

PFAS were not detected above the laboratory reporting limit of 2,050 nanograms per kilogram (ng/kg) in the composite sediment sample collected at a depth interval of 0 to 24 inches. PFAS sediment results are presented on Table 8.

5.0 Conclusions

During three phases between April and October 2017, the Reconnaissance Well Sampling and Investigation Work Plan at the Current, Original and Former Facilities was implemented. The investigation included the installation of 25 borings for collection of soil and grab groundwater samples; sampling of five existing monitoring wells; collection of three surface water samples, three stormwater samples, and 3 composite sediment samples; water level monitoring at existing Site monitoring wells; and completion of a stormwater conveyance survey. The results of the investigation are summarized as follows.

- Shallow Groundwater – PFAS were detected above the SLVs in shallow groundwater. The lateral extent of PFAS impacts above the EPA HA level to shallow groundwater has been delineated to the north, south, and east of the fire training facilities. Further delineation to the west is needed.
- Deep Groundwater – Beneath the fire training facilities, PFAS compounds are present within the Lower OD unit at concentrations above the selected SLVs and in the CRSA at concentrations below the selected SLVs. PFAS compounds were not detected in the sample collected from a well

screened within the CRSA at the PDX QTA Facility, which is between the fire training area and the closest CSSW well, also screened in the CRSA.

- Soil – Concentrations of PFAS detected in soil are below the selected SLVs for an occupational worker; however, select PFAS soil concentrations are above the selected SLV for protection of residential drinking water.
- Stormwater and Surface Water – Stormwater and surface water underneath, in the vicinity of, and downgradient of the impacted area have concentrations that exceed the selected SLV for construction workers; however, at the property boundary and off-site, the PFAS concentrations in surface water are below the construction worker SLV. Detected concentrations of PFAS in stormwater and surface water samples collected during the investigation were below the selected SLVs for aquatic organisms.
- Sediment – PFAS compounds were not detected in sediment collected in the vicinity of the outfall that drains the basin containing the fire training facilities.

Table 1
Stormwater Conveyance System Survey Results
Fire Training Facilities
Portland International Airport
Portland, Oregon

Start Point	Stop Point	Length of Survey (feet)	Site Location	Observations
STSCB3328	STSMH3288	410	Upstream of Former Fire Training Facility	Limited areas of staining from seepage at the joints of the pipe.
STSMH33288	STSMH3303	154		
STSMH3303	STSMH3320	162		
STSMH3320	STSMH3320A	318	Underneath Former Fire Training Facility	Yellow seepage stains were observed, including staining at nearly all pipe joints. Approximately 15 feet downstream from STS MH 3320, an accumulation of yellow sediment was observed at the confluence of a 6-inch diameter lateral. Similar sediment build-up was observed again at a distance of 37 feet. Some small cracks and concrete flaking was observed near pipe joints at several locations. Some sediment accumulation (up to approximately 1-inch thick) was observed at the bottom of the pipe. At 314 feet from STS MH 3320, near the downstream terminus of the segment, a large piece of impassable concrete had flaked off from the wall of catch basin STS MH 3320A.
STSMH3320A	STSMH5094	496	Underneath and downstream of Former Fire Training Facility	At manhole STS MH 3320A, a 4-inch diameter lateral with a filter sock was observed protruding from the south just below the manhole cover. At 18 feet downstream from STS MH 3320A, a large piece of broken concrete was observed at the bottom of the pipe (likely from catch basin STS MH 3320A). At 112 feet downstream from STS MH 3320A, a 6-inch diameter PVC lateral joined the mainline from the south. Yellow staining and minor fractures in the pipe were observed at several locations throughout this segment of pipe. Groundwater seepage and a waxy yellow build-up was observed at several locations between 324 feet and 418 feet downstream of STS MH 3320A. Heavy seepage flow was observed at 334 feet. At 369 feet, seepage and black staining was observed at an access port on the top of the pipe. Heavy staining and seepage was observed in this segment of pipe.

MeFOSAA	Methyl perfluorooctanesulfonamidoacetic acid (C8)	<1.93	<1.94	<1.75	<3.88	--	--
EtFOSAA	Ethyl perfluorooctanesulfonamidoacetic acid (C8)	<1.93	<1.94	<1.75	<3.88	--	--

Notes:

1. ug/kg = Microogram per kilogram (ppt [parts per billion]).
2. Bold values indicate the compound was detected above laboratory reporting limits.
3. < = Compound not detected at or above laboratory reporting limit shown.
4. Risk-based screening levels are EPA RSLs (Industrial, THQ.=1.0) for PFBS, PFOA, and PFOS. All others from State of Texas: Commercial 30 Acres for direct contact; Residential 30 Acres - Ingestion for groundwater protection. See Table A-7
5. Shading indicates the analyte concentration exceeds the protection of groundwater screening level.

Notes:

1. ng/L = Nanogram per liter (ppt [parts per trillion]).
2. Bold values indicate the compounds was detected above laboratory reporting limits.
3. < = Compound not detected at or above laboratory reporting limit shown.
4. J+ = Data results are estimated and may be biased high.
5. H = Sample was extracted outside of the EPA 537 recommended holding time of 14 days.
6. Screening level is residential drinking water: Health advisory limit from the United States Environmental Protection Agency (U.S. EPA) for combined PFOA and PFOS; EPA RSL (THQ=1) for PFBS; and State of Texas for remainder. See Table A-1
7. -- = Value not available.
8. Shading indicates concentration of analyte was detected above the screening level.

	Dissolved	--	--	<0.200	--	<0.200		

Notes:

1. µg/L = Microgram per liter (ppb [parts per billion]).
2. Bold values indicate the constituent was detected above laboratory detection limits.
3. < = Constituent not detected at or above laboratory reporting limit shown.
4. Shading indicates concentration of analyte was detected above at least one applicable risk-based human health screening level.
5. Bold Box cells indicate concentration of analyte was detected above the DEQ Guidance for Ecological Risk Assessment Level II Screening Level Values (Surface Water, Aquatic)
6. Screening level values for Ecological Risk Assessment from DEQ Level II Guidance (Surface Water, Aquatic).
7. Screening level values for human health from DEQ Risk-Based Concentrations (November 1, 2015 revision).
8. -- = Value not available.
9. J = Reported concentration is an estimated value.
10. >S = This groundwater RBC exceeds the solubility limit. Refer to Appendix D for the corresponding value of S. Groundwater concentrations in excess of S indicate that free product may be present. See Section B.2.1.4 for additional information.
11. UJ = Result is estimated and not detected at the specified reporting limit.

	09/06/07	5.05	--	--	12.68
	04/20/17	2.51	--	--	15.22
	09/26/17	4.60	--	--	13.13

Notes:
1. feet MSL = Feet above mean sea level.
2. Casing elevations and groundwater data prior to December 1996 are from a Draft Quarterly Groundwater Monitoring Report dated December 12, 1996, and prepared by Geraghty & Miller.
3. Groundwater data prior to August 2005 were identified from previous report tables and could not be verified by field logs.
4. NM = Water level not measured.
5. -- = No product.
6. Elevation was corrected in wells with the presence of measurable separate-phase petroleum hydrocarbons using the following equation and assuming a specific gravity for gasoline product of 0.8 gram per cubic centimeter (Merck, 1989):

$$h_w = \frac{p_g\, h_g}{p_w}$$

water-level elevation = top of casing elevation + $[h_w - d_w]$

where:

h_w = depth to groundwater correction
d_w = depth to groundwater measuring point
p_g = density of separate-phase hydrocarbons
p_w = density of water
h_g = product thickness

Appendix C

Lithologic Logs

Sample Descriptions

Classification of soils in this report is based on visual field and laboratory observations which include density/consistency, moisture condition, and grain size, and should not be construed to imply field nor laboratory testing unless presented herein. Visual-manual classification methods of ASTM D 2488 were used as an identification guide.

Soil descriptions consist of the following:
MAJOR CONSTITUENT with additional remarks; color, moisture, minor constituents, density/consistency.

Density/Consistency

Soil density/consistency in borings is related primarily to the Standard Penetration Resistance. Soil density/consistency in test pits and push probe explorations is estimated based on visual observation and is presented parenthetically on test pit and push probe exploration logs.

SAND and GRAVEL Density	Standard Penetration Resistance in Blows/Foot
Very loose	0 - 4
Loose	4 - 10
Medium dense	10 - 30
Dense	30 - 50
Very dense	>50

SILT or CLAY Density	Standard Penetration Resistance in Blows/Foot	Approximate Shear Strength in TSF
Very soft	0 - 2	<0.125
Soft	2 - 4	0.125 - 0.25
Medium stiff	4 - 8	0.25 - 0.5
Stiff	8 - 15	0.5 - 1.0
Very Stiff	15 - 30	1.0 - 2.0
Hard	>30	>2.0

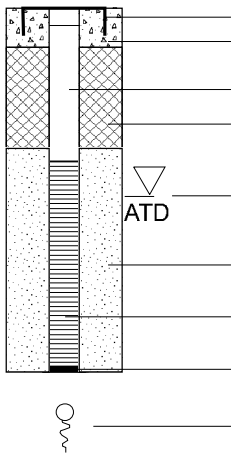
Moisture

Dry	Little perceptible moisture.
Sl. Moist	Some perceptible moisture, probably below optimum.
Moist	Probably near optimum moisture content.
Wet	Much perceptible moisture, probably above optimum.

Minor Constituents

	Estimated Percentage
Not identified in description	0 - 5
Slightly (clayey, silty, etc.)	5 - 12
Clayey, silty, sandy, gravelly	12 - 30
Very (clayey, silty, etc.)	30 - 50

Sampling Symbols



BORING AND PUSH-PROBE SYMBOLS

	Recovery
	No Recovery
	Temporarily Screened Interval
PID	Photoionization Detector Reading
W	Water Sample
	Sample Submitted for Chemical Analysis
NS	No Sheen
SS	Slight Sheen
MS	Moderate Sheen
HS	Heavy Sheen
BF	Biogenic Film

TEST PIT SOIL SAMPLES

	Grab (Jar)
	Bag
	Shelby Tube

Groundwater Observations and Monitoring Well Construction

Flush Mounted Monument

Appendix D

Laboratory Quality Assurance/Quality Control Review and Analytical Laboratory Reports

Appendix D – Analytical Laboratory Reports and Quality Assurance / Quality Control Review

1.0 Introduction

This appendix documents the results of a quality assurance/quality control (QA/QC) review of the analytical data for soil and groundwater samples collected at the Portland International Airport Fire Training Facilities, Portland, Oregon. Samples from the Site were analyzed by Apex Laboratories of Tigard, Oregon, Vista Analytical Laboratory of El Dorado Hill, California, and TestAmerica of West Sacramento, California. Copies of the analytical laboratory reports are included in this appendix, referenced in Table 1 as follows:

Table 1: Analytical Laboratory Reports

Report	Report Date	Sampling Event
A7J0065	October 20, 2017	Site Investigation
1701173	September 26, 2017	Site Investigation
1701175	October 18, 2017	Site Investigation
1701384	October 27, 2017	Site Investigation
1701385	October 27, 2017	Site Investigation
1701392	October 25, 2017	Site Investigation
1701412	October 30, 2017	Site Investigation
J32175	October 30, 2017	Site Investigation

2.0 Data Validation

The QA review outlines the applicable quality control criteria utilized during the data review process, as well as any deviations from those criteria. Examination and validation of the laboratory summary reports include:

- Analytical preparation and quantitation methods
- Analytical method holding times
- Sample handling
- Chain of custody handling
- Detection and reporting limits
- Analyte identification and quantitation
- Method blank, trip blank and equipment blank detections
- Laboratory control samples, matrix spikes, surrogates and on-going precision/recovery (OPR) to assess laboratory accuracy

- Laboratory control sample duplicates and laboratory duplicates to assess laboratory precision
- Field duplicates to assess sampling and laboratory precision

The QA/QC review did not include a review of raw data.

This QA/QC review documents the relationship between analytical findings and data quality objectives based on precision and accuracy. It also summarizes possible error or bias and the effect on data quality and usability.

The laboratory quality control (QC) samples provided in data packages were used to evaluate laboratory contamination or background interferences, sample preparation efficiency, instrumentation performance and sample matrix interferences. The QC samples provided by the analytical laboratories include: method blanks, laboratory control samples (LCS/LCSD), ongoing precision and accuracy (OPR), matrix spikes (MS) and laboratory duplicates. Surrogates and labeled standards were also analyzed to assess sample preparation efficiency and matrix interferences.

2.1 Data Qualifiers

Any data that is found to have possible bias or error was qualified and flagged. The following are flags used in this QA/QC review and data tables.

Table 2: Qualifier Flags

J	Data results are estimated values. Concentrations associated with this qualifier are approximate.
J+	Data results are estimated values and may be biased high.
UJ	The not detected result is estimated at the specified reporting limit.

3.0 Analytical Methods

Chemical analyses consisted of the following:

- Volatile organic compounds (VOC) by U.S. Environmental Protection Agency (EPA) method 8260C
- Diesel and oil by NWTPH-Dx with silica gel cleanup
- Polychlorinated biphenyls (PCBs) by EPA method 8082A
- Polyaromatic hydrocarbons (PAHs) by EPA method 8270D with selective ion monitoring (SIM)

- Total and dissolved arsenic, barium, cadmium, chromium, lead, mercury, selenium and silver by EPA method 6020A
- Per- and polyfluorinated alkyl substances (PFC) by modified EPA method 537
- Total oxidizable precursor (TOP) assay, pre- and post- treatment analysis of PFCs

4.0 Data Quality Assurance Review

The general QA objectives for this project were to develop and implement procedures for obtaining, evaluating, and confirming the usability of data of a specified quality. To collect such information, analytical data must have an appropriate degree of accuracy and reproducibility, samples collected must be representative of actual field conditions, and samples must be collected and analyzed using unbroken chain-of-custody procedures.

Reporting limits and analytical results were compared to cleanup and screening levels for each parameter in the matrix of concern. Precision, accuracy, completeness, and comparability parameters used to indicate data quality are defined below.

4.1 Holding Times and Sample Receipt

The holding time is the minimum amount of time the sample can be stored before analytes start to degrade and are not representative of initial sampling concentrations. Holding times are defined by analytical methods.

The 14-day holding time was violated for analysis of PFHxA, PFHxS and PFOS in samples B-T-GW, B-O-GW, B-U-GW, B-N-GW, B-G-GW, B-F-GW, B-S-GW, B-R-GW, B-Q-GW, B-P-GW, MH-1, MH-2, OF1N-NW and SW-1. Samples were re-extracted since the initial extraction and analysis produced detectable concentrations of PFOS, PFHxS and PFHxA in the method blank. Re-extraction was performed to mitigate possible contamination and elevated results for these analytes. Due to the stability of these analytes within the matrix and sample storage conditions at the laboratory, changes in sample concentration because of this holding time violation are not likely.

Samples were received intact and unbroken upon receipt by the analytical laboratories. Groundwater samples were received on ice and without headspace in VOA sampling containers. Samples with an acid preservative were pH checked upon arrival by the laboratory for method compliance.

All chain-of-custodies were appropriately relinquished by Apex Companies personnel and received by the designated analytical laboratory. They were filled out with the correct sample ID, sampling date, sampling time and analyses requested. Discrepancies found between the bottles and the chain of custodies were

resolved through Apex Companies project management and record of that communication is available within the laboratory reports.

4.2 Reporting Limits and Detection Limits

Reporting limits are the lowest concentration an instrument is capable of accurately detecting an analyte. They are determined by the laboratory and are based on instrumentation capabilities, the matrix of field samples, sample preparation procedures and EPA suggested reporting limits.

The method detection limit (MDL) is the minimum concentration that an analyte can be reported where it is 99% confident that the analyte is greater than zero. Any analyte that is reported between the method detection limit and the reporting limit is an estimated value and "J" flagged accordingly.

In most cases, detection limits were below promulgated screening values. Reporting limits for perfluoroalkyl substances (PFAS) were consistent with historical data.

4.3 Analyte Identification and Quantitation

For analysis of PFAS, the recovery of some labeled standards was outside of control limits. Labeled standards are spiked directly into samples before preparation to determine matrix interferences and concentration of analytes. Recovery of these labeled standards automatically corrects sample concentration due to isotope dilution. Data quality is not considered affected if the signal-to-noise ratio is greater than 10:1, which was achieved. No data is flagged in the data table.

The recovery of labeled standard M2-4:2 FTS for the post-treatment analyses in report J32175 was at 0%. This standard is added to samples before oxidation and monitors the oxidations efficiency. A 0% recovery indicates 100% complete oxidation of the M2-4:2 FTS standard. This standard is not used to quantitate any target analytes.

4.4 Method Blanks

A method - or laboratory - blank is a quality control sample prepared by the laboratory from an analyte-free matrix and analyzed in an analytical batch along with environmental and other QC samples. It is used to assess laboratory contamination or background interferences. There were no detections of analytes in the method blanks except for PFOS in report 1701173. PFOS was detected above the reporting limit at 1.73 nanograms per liter (ng/L). Groundwater samples associated with this QC batch (B7I0079) that concentrations of PFOS less than ten times the method blank concentration are "J+" flagged as estimated values with a possible high bias. If concentrations of PFOS within the samples is greater than ten times the method blank concentration, any possible laboratory contamination is considered insignificant compared to concentrations found in the samples.

The method blank results for post-treatment TOP assay included a detection of PFBA above the reporting limit. This detection is a result of the oxidation of M2-4:2 FTS, added to the sample by the laboratory before preparation to track the efficiency of the oxidation preparation performed. This compound was also added to MW-4 to track oxidation efficiency and the resulting amount of PFBA generated is not considered to significantly increase the amount of PFBA in the sample. See Table 3.

4.5 Trip Blank

A trip blank is an analyte-free matrix that is collected in the laboratory and is shipped along with the sample bottles to the field, kept with the soil and groundwater samples during collection, and shipped back to the laboratory with the field samples. The trip blank is analyzed for volatile organic compounds (VOCs) of interest, along with the primary samples, to assess if detected contaminants may have been the result of contamination of the samples during transport or storage. One trip blank was analyzed and no VOC analytes were detected.

4.6 Equipment Blank

An equipment blank is a sample of analyte-free water poured over or through decontaminated field sampling equipment during a sampling event. Equipment blanks assess contamination from the total sampling, sample preparation, and measurement process when decontaminated sampling equipment is used to collect samples. Two equipment blanks were analyzed for PFAS, one for each groundwater sampling method used. The equipment blank collected 9/26/2017 had concentrations of PFHxS, PFOA and PFOS above the reporting limit. Affected groundwater samples include B-A-GW, B-B-GW, B-C-GW, B-D-GW, B-L-GW, B-R-GW, B-S-GW, and B-W-GW; where concentrations of PFOA and/or PFOS were less than ten times the equipment blank concentration. Sample data is "J+" flagged as estimated values with a possible high bias.

4.7 Accuracy

Accuracy compares the accepted reference concentration of an analyte to the concentration determined analytically. Accuracy is measured as a percent recovery. This recovery must be within a certain range - or control limit - for the data in an analytical batch to be considered acceptable. The analytical laboratory provides quality control samples and surrogates to help determine the accuracy and acceptability of the data reported. These quality control samples and surrogates are discussed below.

4.7.1 Laboratory Control Samples/Ongoing Precision and Recovery (OPR)

Laboratory control samples (LCS) and laboratory control duplicate samples (LCSD) were analyzed by the laboratory to assess the accuracy of the analytical methods. The LCS and LCSDs are prepared from an analyte-free matrix that is spiked with known levels of compounds of concern. The concentrations are measured and compared to the known spiked levels; expressed as a percent recovery. This percent recovery

must be within method or laboratory defined control limits for data to be considered acceptable. Ongoing precision and recovery (OPR) quality control samples were analyzed in place of LCS/LCSDs for PFAS analysis.

Chloromethane and bromomethane were recovered above the upper control limit for batch 7100417. Groundwater samples associated with these batches did not have detectable concentrations of chloromethane or bromomethane and the high recovery is due to the analyte not meeting calibration criteria; no data were flagged.

The recovery for PFTrDA was 9% above the upper control limit in report 1701392. The associated sediment sample (OF-1N-Mix) did not have detectable concentrations for PFTrDA so no data were flagged.

For the post-treatment TOP assay analysis, the LCS/LCSD had a recovery of PFBA, PFPeA, PFHxA, PFHpA and PFOA above the upper control limit. Additionally, FOSA, 6:2 FTS and 8:2 FTS were not recovered at all within the LCS/LCSD. Sample data is accepted since FOSA, 6:2 FTS and 8:2 FTS are oxidizable precursors to perfluoroinated carboxylic acids (PFCAs) like PFPeA, PFHxA, PFHpA and PFOA. Because the LCS/LCSD was spiked with target analytes and then oxidized, these precursors were transformed into controlled PFCAs resulting in elevated recoveries. See Table 3 below for possible end products from LCS/LCSD precursors.

Table 3: PFCA Precursors and End Products after Oxidation

PFCA Precursor	Possible End Products
FOSA	PFOA (C8)
6:2 FTS	PFHxA (C6)
	PFPeA (C5)
	PFBA (C4)
8:2 FTS	PFOA (C8)
	PFHpA (C7)
	PFHxA (C6)
	PFPeA (C5)
	PFBA (C4)
M2-4:2 FTS	PFBA (C4)

4.7.2 Matrix Spikes

A matrix spike QC sample is used to assess the performance of the analytical method by determining potential matrix interferences. Matrix spike (MS) and matrix spike duplicate (MSD) analyses are performed on one environmental sample per analytical batch. A matrix spike sample uses an environmental sample that is spiked with known concentrations of analytes of interest. The matrix spike is then prepared and analyzed with

the same analytical procedures as environmental samples in the analytical batch. The resulting concentration of the matrix spike is then compared to the known - or true - values plus the non-spiked environmental sample concentration. This comparison is expressed as a percent recovery.

Cis-1,3-dichloropropene was recovered below the lower control limit in report A7J0065. This analyte may be biased low in the original source sample (B-J-GW) and the result is "UJ" flagged in the data table as an estimated reporting limit.

4.7.3 Surrogates

Surrogates are organic compounds that are similar in chemical composition to the analytes of interest but are not likely to be found in the environment. They are spiked at a known concentration into environmental and batch QC samples prior to sample preparation and analysis. Surrogate recoveries for environmental samples are used to evaluate matrix interference, sample preparation efficiency and analysis performance on a sample-specific basis. Surrogate percent recoveries for quality control samples and groundwater samples were within control criteria.

4.8 Precision

Precision is measured by how close values of duplicate analyses are to each other. These duplicate analyses are prepared from separate aliquots of the same sample and are analyzed at the same (or similar) time. Precision in the field ensures that samples taken are representative of field concentrations; this is demonstrated by field duplicates. Analytical precision is the ability of the laboratory to reproduce results that are similar to each other; this is measured through duplicate analysis of environmental and batch QC samples. Precision is estimated by the relative percent difference (RPD) between the original analysis and the duplicate analysis.

4.8.1 Laboratory Control Samples

The analytical batch LCS concentration of an analyte is compared to the LCSD concentration of the same analyte. The relative percent difference (RPD) is calculated from these two concentrations; which must be below a certain percentage to be considered acceptable. RPD values between LCS and LCSD pairs in QC batches were within the control limits.

4.8.2 Laboratory Duplicate

A laboratory duplicate is a second analysis of an environmental sample received by the laboratory, which serves as an internal check on laboratory quality as well as potential variability of the sample matrix. The laboratory duplicate is analyzed and compared to the primary sample analysis to assess the precision of the

analytical method. This comparison can be expressed by the RPD between the original and duplicate samples. RPD values were within control limits as defined by the laboratory.

4.8.3 Field Duplicate

A field duplicate is a second field sample collected from a selected sample location. Field duplicate samples serve as a check on laboratory precision, sampling quality, as well as potential variability of the sample matrix. The field duplicate is analyzed and compared to the original sample to assess precision. This comparison can be expressed by the RPD between the original and duplicate samples. Field duplicate samples are only controlled if the reported result is greater than 5 times the reporting limit. Field duplicates were collected from B-I-GW and MW-6 and RPD values were below the 30% control limit.

5.0 Conclusion

In conclusion, the QA objectives have been met and the data are of sufficient quality for use in this project.

Notes and Definitions

Qualifiers:

C-07	Extract has undergone Sulfuric Acid Cleanup by EPA 3665A, Sulfur Cleanup by EPA 3660B, and Florisil Cleanup by EPA 3620B in order to minimize matrix interference.
J	Estimated Result. Result detected below the lowest point of the calibration curve, but above the specified MDL.
Q-01	Spike recovery and/or RPD is outside acceptance limits.
Q-16	Reanalysis of an original Batch QC sample.
Q-19	Blank Spike Duplicate (BSD) sample analyzed in place of Matrix Spike/Duplicate samples due to limited sample amount available for analysis.
Q-42	Matrix Spike and/or Duplicate analysis was performed on this sample. % Recovery or RPD for this analyte is outside laboratory control limits. (Refer to the QC Section of Analytical Report.)
Q-54	Daily Continuing Calibration Verification recovery for this analyte failed the +/-20% criteria listed in EPA method 8260C/8270D by +1%. The results are reported as Estimated Values.
Q-54a	Daily Continuing Calibration Verification recovery for this analyte failed the +/-20% criteria listed in EPA method 8260C/8270D by +7%. The results are reported as Estimated Values.
Q-56	Daily CCV/LCS recovery for this analyte was above the +/-20% criteria listed in EPA 8260C

Notes and Conventions:

DET	Analyte DETECTED
ND	Analyte NOT DETECTED at or above the reporting limit
NR	Not Reported
dry	Sample results reported on a dry weight basis. Results listed as 'wet' or without 'dry'designation are not dry weight corrected.
RPD	Relative Percent Difference
MDL	If MDL is not listed, data has been evaluated to the Method Reporting Limit only.
WMSC	Water Miscible Solvent Correction has been applied to Results and MRLs for volatiles soil samples per EPA 8000C.
Batch QC	Unless specifically requested, this report contains only results for Batch QC derived from client samples included in this report. All analyses were performed with the appropriate Batch QC (including Sample Duplicates, Matrix Spikes and/or Matrix Spike Duplicates) in order to meet or exceed method and regulatory requirements. Any exceptions to this will be qualified in this report. Complete Batch QC results are available upon request. In cases where there is insufficient sample provided for Sample Duplicates and/or Matrix Spikes, a Lab Control Sample Duplicate (LCS Dup) is analyzed to demonstrate accuracy and precision of the extraction and analysis.
Blank Policy	Apex assesses blank data for potential high bias down to a level equal to ½ the method reporting limit (MRL), except for conventional chemistry and HCID analyses which are assessed only to the MRL. Sample results flagged with a B or B-02 qualifier are potentially biased high if they are less than ten times the level found in the blank for inorganic analyses or less than five times the level found in the blank for organic analyses. For accurate comparison of volatile results to the level found in the blank; water sample results should be divided by the dilution factor, and soil sample results should be divided by 1/50 of the sample dilution to account for the sample prep factor. Results qualified as reported below the MRL may include a potential high bias if associated with a B or B-02 qualified blank. B and B-02 qualifications are not applied to J qualified results reported below the MRL.

Vista Work Order No. 1701173

Ms. Ashleigh Fines
Apex Companies, LLC
3015 SW First Avenue
Portland, OR 97201

Dear Ms. Fines,

Enclosed are the amended results for the sample set received at Vista Analytical Laboratory on August 31, 2017. This sample set was analyzed on a standard turn-around time, under your Project Name 'PDX Fire Training Facility'.

Vista Analytical Laboratory is committed to serving you effectively. If you require additional information, please contact me at 916-673-1520 or by email at mmaier@vista-analytical.com.

Thank you for choosing Vista as part of your analytical support team.

Sincerely,

Martha Maier
Laboratory Director

Vista Analytical Laboratory certifies that the report herein meets all the requirements set forth by NELAP for those applicable test methods. Results relate only to the samples as received by the laboratory. This report should not be reproduced except in full without the written approval of Vista.

Vista Work Order No. 1701173
Case Narrative

Sample Condition on Receipt:

Fourteen aqueous samples and six soil samples were received in good condition and within the method temperature requirements. The samples were received and stored securely in accordance with Vista standard operating procedures and EPA methodology. The soil samples, currently on hold, were assigned to Vista Work Order No. 1701175. This report was amended to revise the narrative and include the results from additional extract dilutions.

Analytical Notes:

Modified EPA Method 537

The aqueous samples were extracted and analyzed for a selected list of 14 PFAS using Modified EPA Method 537. The results for PFHxS, PFOA and PFOS include both linear and branched isomers. Results for all other analytes include the linear isomers only.

Holding Times

The samples were extracted and analyzed within the method hold times. The samples were re-extracted due to detections of PFOS, PFHxS and PFHxA in the Method Blank. The re-extractions were performed outside of the hold time. The results for all other analytes were reported from the original extractions.

Quality Control

The Initial Calibration and Continuing Calibration Verifications met the acceptance criteria.

A Method Blank and Ongoing Precision and Recovery (OPR) sample were extracted and analyzed with each preparation batch. The detected concentrations of PFOS, PFHxA and PFHxS were above the Reporting Limits in Method Blank B7H0199. No other analytes were detected in the Method Blanks above the Reporting Limits. The OPR recoveries were within the method acceptance criteria.

The labeled standard recoveries outside the acceptance criteria are listed in the table below.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

DATA QUALIFIERS & ABBREVIATIONS

B	**This compound was also detected in the method blank.**
D	**Dilution**
E	**The associated compound concentration exceeded the calibration range of the instrument.**
H	**Recovery and/or RPD was outside laboratory acceptance limits.**
I	**Chemical Interference**
J	**The amount detected is below the Reporting Limit/LOQ.**
M	**Estimated Maximum Possible Concentration. (CA Region 2 projects only)**
*****	**See Cover Letter**
Conc.	**Concentration**
NA	**Not applicable**
ND	**Not Detected**
TEQ	**Toxic Equivalency**
U	**Not Detected (specific projects only)**

Unless otherwise noted, solid sample results are reported in dry weight. Tissue samples are reported in wet weight.

Vista Work Order No. 1701175

Ms. Ashleigh Fines
Apex Companies, LLC
3015 SW First Avenue
Portland, OR 97201

Dear Ms. Fines,

Enclosed are the results for the sample set received at Vista Analytical Laboratory on August 31, 2017. This sample set was analyzed on a standard turn-around time, under your Project Name 'PDX Fire Training Facility'.

Vista Analytical Laboratory is committed to serving you effectively. If you require additional information, please contact me at 916-673-1520 or by email at mmaier@vista-analytical.com.

Thank you for choosing Vista as part of your analytical support team.

Sincerely,

Karen J. Volpendesta for

Martha Maier
Laboratory Director

Vista Analytical Laboratory certifies that the report herein meets all the requirements set forth by NELAP for those applicable test methods. Results relate only to the samples as received by the laboratory. This report should not be reproduced except in full without the written approval of Vista.

Vista Work Order No. 1701175
Case Narrative

Sample Condition on Receipt:

Twenty soil samples were received in good condition and within the method temperature requirements. The samples were received and stored securely in accordance with Vista standard operating procedures and EPA methodology. Per client request upon receipt, all samples were placed on hold. As requested, samples "B-F-1 (6-12")" and "B-G-1 (6-12")" were removed from hold on September 27, 2017.

It was noted that Sample ID "B-U-1 (6-12')" on the Chain-of-Custody (CoC) did not match the Sample ID on the bottle of "B-U-1 (6.5-12')". Per client request, the Sample ID from the CoC was used for sample reporting. Also, sample "B-P-2 (3.5-4')" had a collection time on the CoC of "1311" but the bottle collection time was "1402". Per client request, "1402" is the correct collection time.

Analytical Notes:

VAL-PFAS

The samples were extracted and analyzed for a selected list of PFAS using VAL Method PFAS. The results for PFHxS, PFOA and PFOS include both linear and branched isomers. Results for all other analytes include the linear isomers only.

Holding Times

The samples were extracted and analyzed within the method hold times.

Quality Control

The Initial Calibration and Continuing Calibration Verifications met the acceptance criteria.

A Method Blank and Ongoing Precision and Recovery (OPR) sample were extracted and analyzed with the preparation batch. No analytes were detected in the Method Blank above the Reporting Limit. The OPR recoveries were within the method acceptance criteria.

The labeled standard recoveries outside the acceptance criteria are listed in the table below.

QC Anomalies

LabNumber	SampleName	Analysis	Analyte	Flag	%Rec
B7J0006-BLK1	B7J0006-BLK1	VAL - PFAS	13C2-PFUnA	H	58.4

H = Recovery was outside laboratory acceptance criteria.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
The results are reported in dry weight.
The sample size is reported in wet weight.
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
The results are reported in dry weight.
The sample size is reported in wet weight.
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

Sample ID: B-F-1 (6-12')

VAL - PFAS

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
The results are reported in dry weight.
The sample size is reported in wet weight.
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

DATA QUALIFIERS & ABBREVIATIONS

B	**This compound was also detected in the method blank.**
D	**Dilution**
E	**The associated compound concentration exceeded the calibration range of the instrument.**
H	**Recovery and/or RPD was outside laboratory acceptance limits.**
I	**Chemical Interference**
J	**The amount detected is below the Reporting Limit/LOQ.**
M	**Estimated Maximum Possible Concentration. (CA Region 2 projects only)**
*****	**See Cover Letter**
Conc.	**Concentration**
NA	**Not applicable**
ND	**Not Detected**
TEQ	**Toxic Equivalency**
U	**Not Detected (specific projects only)**

Unless otherwise noted, solid sample results are reported in dry weight. Tissue samples are reported in wet weight.

Phone:	(503) 924-4704		

Please review the following information and complete the Client Authorization section. To comply with NELAC regulations, we must receive authorization before proceeding with sample analysis.

Thank you,

Martha Maier
mmaier@vista-analytical.com
916-673-1520

The following information or item is needed to proceed with analysis:

☐ Complete Chain-of-Custody	☐ Preservative	☐ Collector's Name
☐ Test Method Requested	☐ Sample Identification	☐ Sample Type
☐ Analyte List Requested	☒ Sample Collection Time: **See**	☐ Sample Location
☐ Other:		

The following anomalies were noted. Authorization is needed to proceed with analysis.

☐ Temperature outside < 6°C Range Samples Affected: _____

Temperature _____°C Ice Present? Yes No Melted

☒ Sample ID Discrepancy: **See Comments**	☐ Insufficient Sample Size
☐ Sample Holding Time Missed	☐ Sample Container(s) Broken
☐ Custody Seals Broken	☐ Incorrect Container Type

Comments: Sample: B-P-2 (3.5-4') collection time on COC:**1311** collection time on sample label: **1402** Do not match

COC ID:	Sample label ID
B-U-1 (6-12')	B-U-1 (6.5-12')

Client Authorization

Proceed with Analysis: (YES) NO Signature and Date Karen J. Noth 10-18-17

Client Comments/Instructions Per email from client on 9-7-17, the correct collection time for B-P-2 (3.5-4') is 1402. The sample ID of "B-U-1 (6-12')".

October 27, 2017

Vista Work Order No. 1701384

Ms. Ashleigh Fines
Apex Companies, LLC
3015 SW First Avenue
Portland, OR 97201

Dear Ms. Fines,

Enclosed are the results for the sample set received at Vista Analytical Laboratory on October 04, 2017. This sample set was analyzed on a standard turn-around time, under your Project Name 'PDX Fire Training Facility'.

Vista Analytical Laboratory is committed to serving you effectively. If you require additional information, please contact me at 916-673-1520 or by email at mmaier@vista-analytical.com.

Thank you for choosing Vista as part of your analytical support team.

Sincerely,

Martha Maier
Laboratory Director

Vista Analytical Laboratory certifies that the report herein meets all the requirements set forth by NELAP for those applicable test methods. Results relate only to the samples as received by the laboratory. This report should not be reproduced except in full without the written approval of Vista.

Vista Work Order No. 1701384
Case Narrative

Sample Condition on Receipt:

Nine groundwater samples were received in good condition and within the method temperature requirements. The samples were received and stored securely in accordance with Vista standard operating procedures and EPA methodology. As requested, sample "Cascade Water" was placed on hold. The TOP Assay was subcontracted and the results will be reported separately.

Analytical Notes:

Modified EPA Method 537

The samples were extracted and analyzed for a selected list of PFAS using Modified EPA Method 537. The results for PFHxS, PFOA and PFOS include both linear and branched isomers. Results for all other analytes include the linear isomers only.

Holding Times

The samples were extracted and analyzed within the method hold times.

Quality Control

The Initial Calibration and Continuing Calibration Verifications met the acceptance criteria.

A Method Blank and Ongoing Precision and Recovery (OPR) sample were extracted and analyzed with the preparation batch. No analytes were detected in the Method Blank above the Reporting Limit. The OPR recoveries were within the method acceptance criteria.

The recoveries of all internal standards in the QC and field samples were within the acceptance criteria.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

Vista Work Order No. 1701385

Ms. Ashleigh Fines
Apex Companies, LLC
3015 SW First Avenue
Portland, OR 97201

Dear Ms. Fines,

Enclosed are the results for the sample set received at Vista Analytical Laboratory on October 04, 2017. This sample set was analyzed on a standard turn-around time, under your Project Name 'PDX Fire Training Facility'.

Vista Analytical Laboratory is committed to serving you effectively. If you require additional information, please contact me at 916-673-1520 or by email at mmaier@vista-analytical.com.

Thank you for choosing Vista as part of your analytical support team.

Sincerely,

Martha Maier
Laboratory Director

Vista Analytical Laboratory certifies that the report herein meets all the requirements set forth by NELAP for those applicable test methods. Results relate only to the samples as received by the laboratory. This report should not be reproduced except in full without the written approval of Vista.

Vista Work Order No. 1701385
Case Narrative

Sample Condition on Receipt:

Thirteen groundwater samples were received in good condition and within the method temperature requirements. The samples were received and stored securely in accordance with Vista standard operating procedures and EPA methodology.

Analytical Notes:

Modified EPA Method 537

The samples were extracted and analyzed for a selected list of PFAS using Modified EPA Method 537. The results for PFHxS, PFOA and PFOS include both linear and branched isomers. Results for all other analytes include the linear isomers only.

Holding Times

The samples were extracted and analyzed within the method hold times.

Quality Control

The Initial Calibration and Continuing Calibration Verifications met the acceptance criteria.

A Method Blank and Ongoing Precision and Recovery (OPR) sample were extracted and analyzed with the preparation batch. No analytes were detected in the Method Blank above the Reporting Limit. The OPR recoveries were within the method acceptance criteria.

The labeled standard recoveries outside the acceptance criteria are listed in the table below.

QC Anomalies

LabNumber	SampleName	Analysis	Analyte	Flag	%Rec
1701385-06	B-H-GW	Modified EPA Method 537	13C2-PFUnA	H	57.7
B7J0060-BLK1	B7J0060-BLK1	Modified EPA Method 537	13C2-PFUnA	H	55.2

H = Recovery was outside laboratory acceptance criteria.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

RL - Reporting limit

LCL-UCL- Lower control limit - upper control limit
Results reported to RL.
When reported, PFHxS, PFOA and PFOS include both linear and branched isomers.
Only the linear isomer is reported for all other analytes.

Sample ID: B-K-GW

Modified EPA Method 537

Client Data

Name: Apex Companies, LLC
Project: PDX Fire Training Facility
Matrix: Groundwater
Date Collected: 28-Sep-17 09:03

Laboratory Data

Lab Sample: 1701385-09
Date Received: 04-Oct-17 09:35
